# Peritoneal Dialysis in ICU

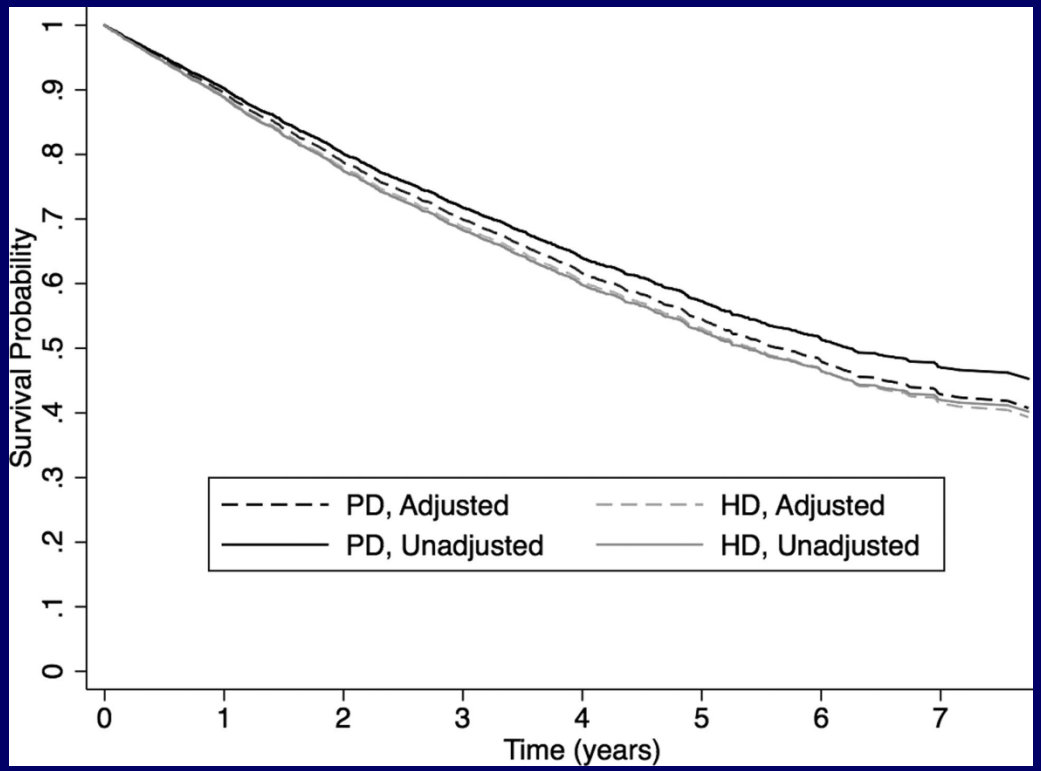
Iraj Najafi MD.

**Fouman**

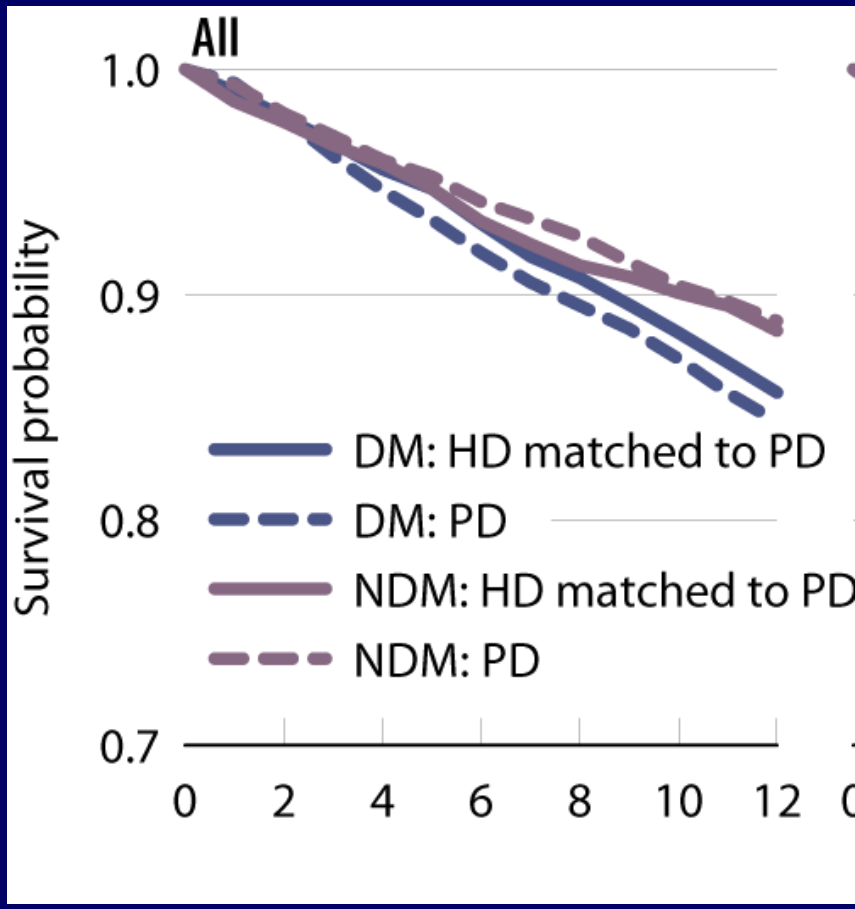
11/2/1397

# No Real Difference in Outcomes of PD and HD Patients with ESRD: US, Canada, Holland

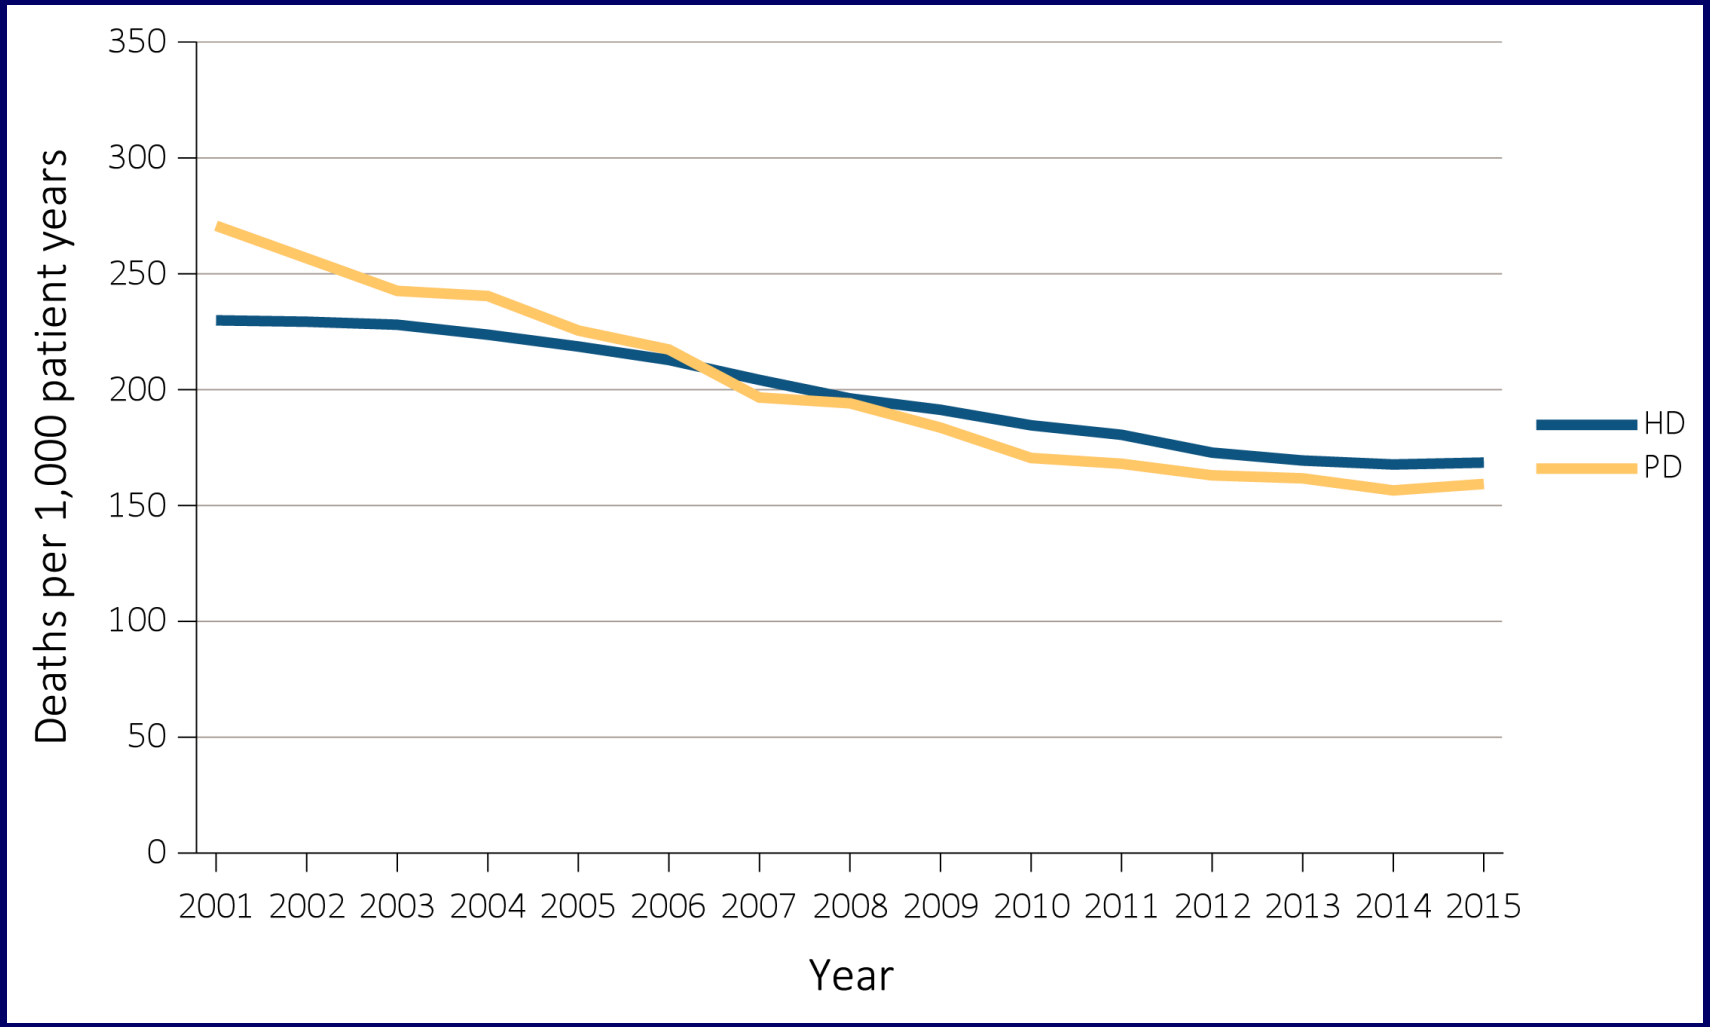
Selection Bias: Survival in Ontario Registry for PD and HD pts who had received at least 4 mths of predialysis care & started dialysis electively, as outpatients. (Quinn et al: J Am Soc Nephrol. 2011 22:1534



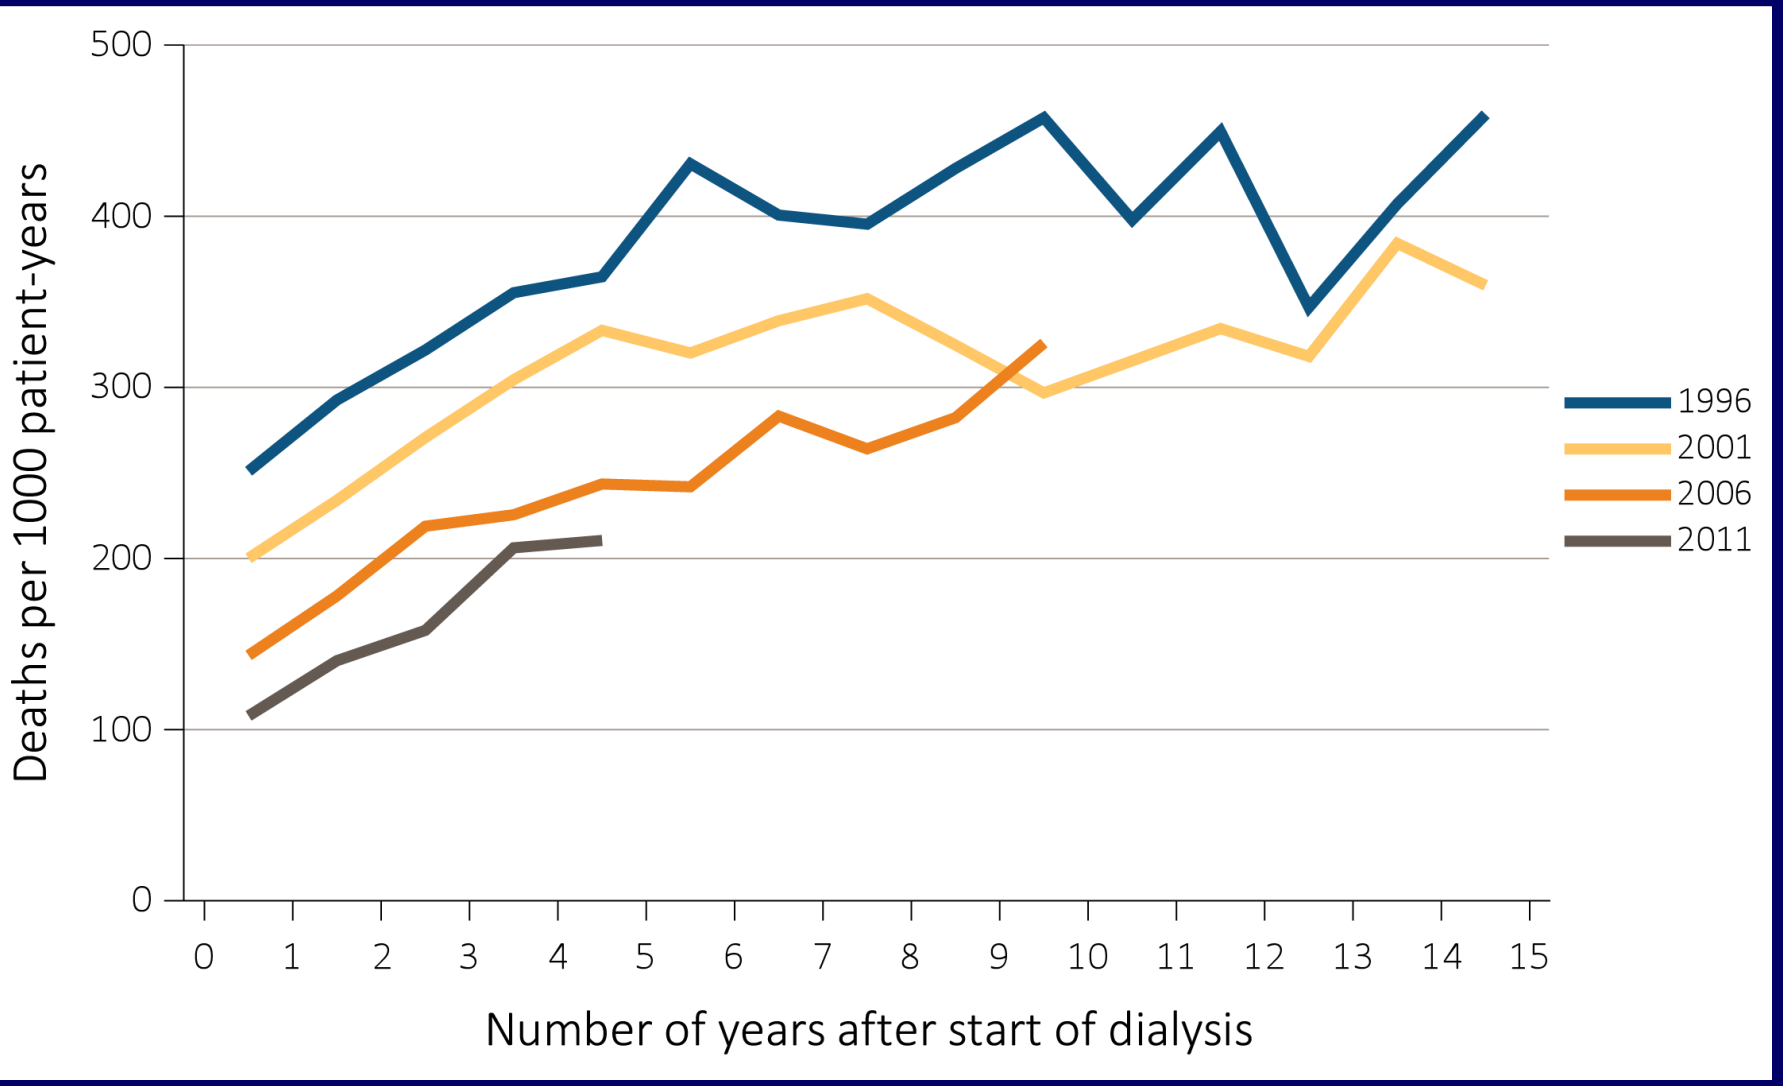
USRDS 2012: survival using propensity-matched modality data by race & diabetic status



# Decline in Mortality Over Time: USRDS 2017



# PD Mortality By Time of Start USRDS 2017

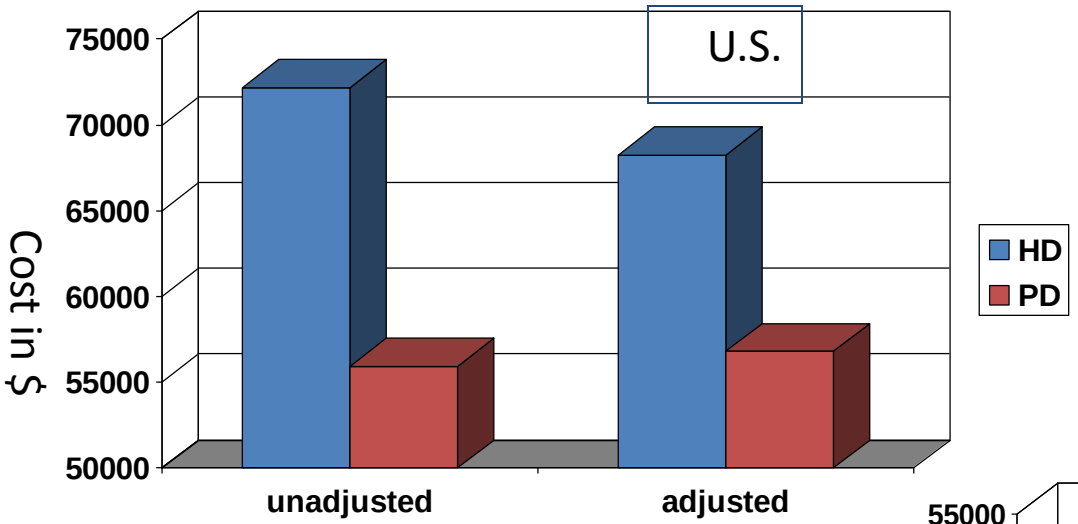


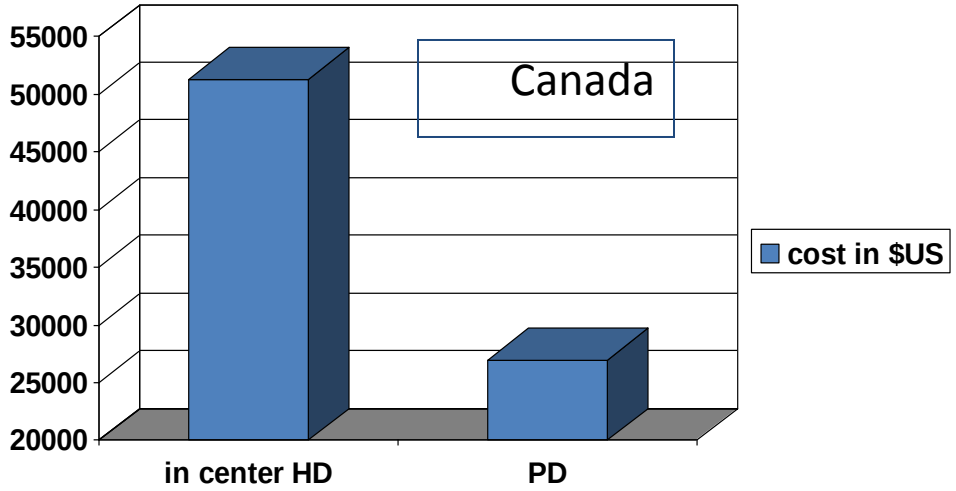
# What Drives the Improvements in PD Outcomes?

- Decrease in peritonitis rates
- Decrease in exit site infections
- Better management of infections
- Improvements in catheter placement
- Better understanding of the “dose” of dialysis
- Better management of ultrafiltration (icodextrin, understanding U/F failure, etc)

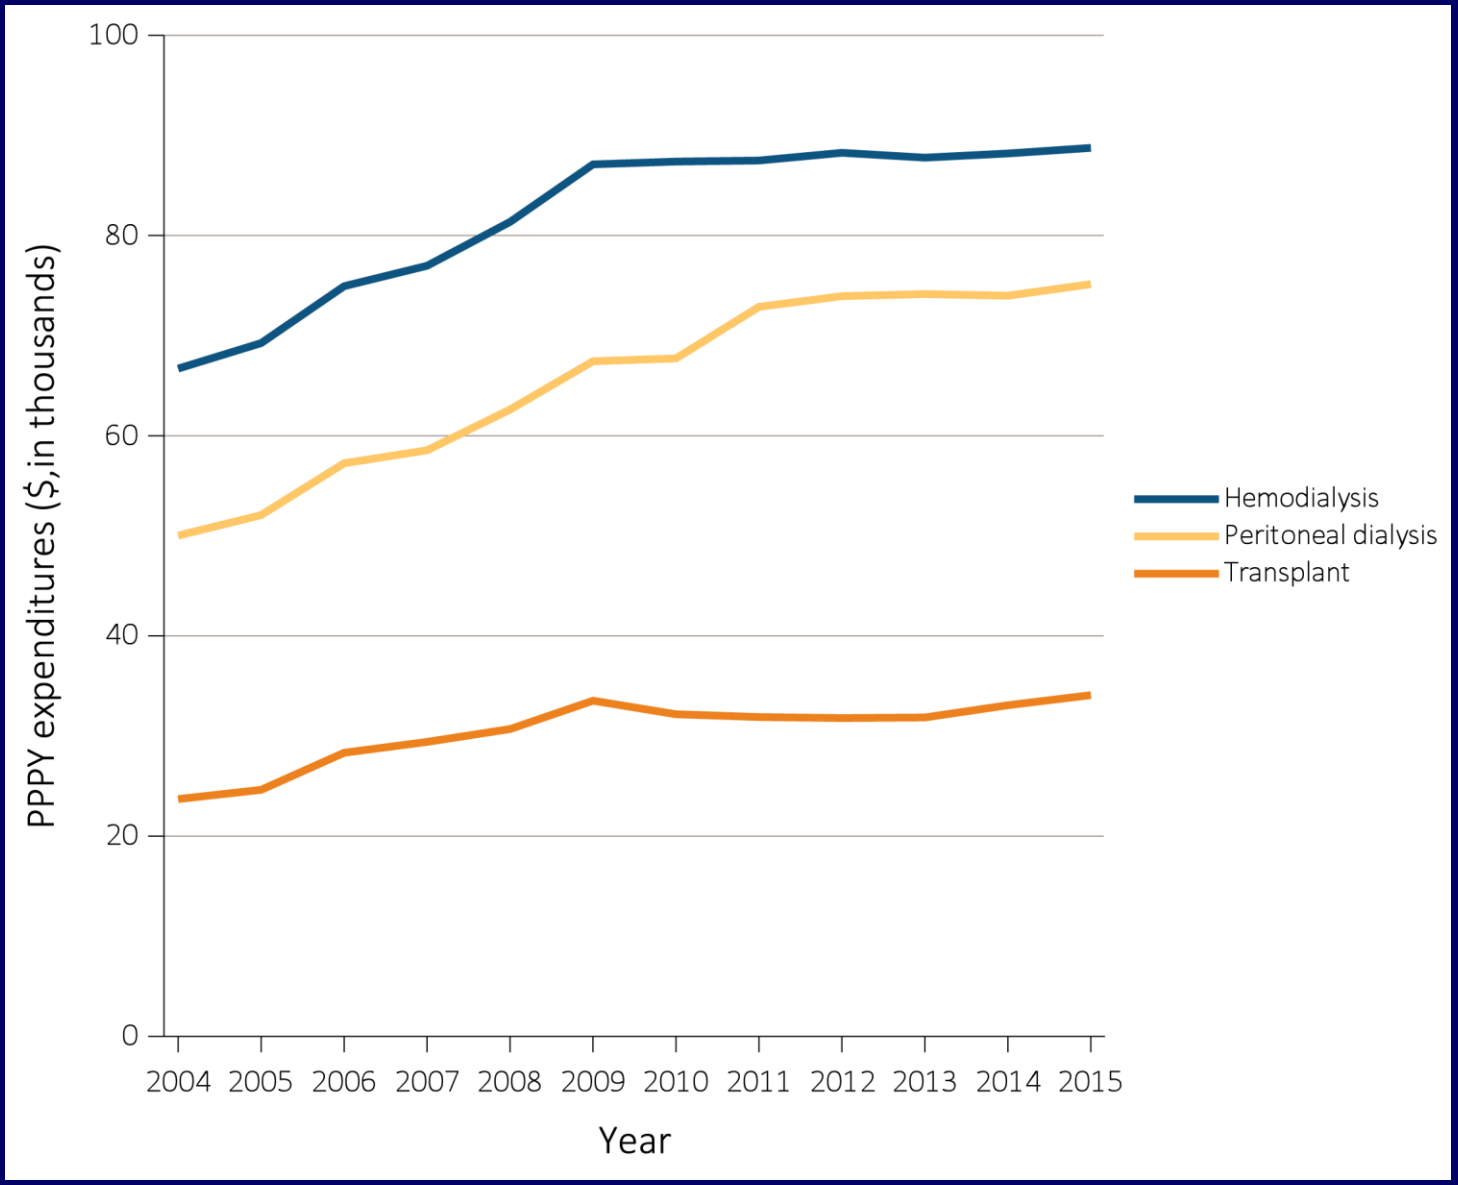
# GLOBAL COSTS: PD vs HD

(Lee: AJKD 40,611,2002; Shih: KI 68:319, 2005)





# *USRDS 2017:* Total Medicare ESRD expenditures per person per year 2004-2015



# PD in AKI

# Urgent Start PD

Iraj Najafi MD

Kish Nephrology Urology congress

۱۶ آذر ۱۳۹۶

# Urgent-start PD:

## *Definition*

- Initiation of peritoneal dialysis in patients with unplanned incident end-stage renal disease (ESRD) who are not yet on dialysis and who require dialysis initiation before the traditional waiting period of 2 or more weeks after PD catheter placement, but do not require emergent dialysis.

# *Protocol for*

# Urgent-start PD

Dr. Mohamed Alamin

# Catheter Insertion

- Who should place the PD catheter?

**Expert personnel**

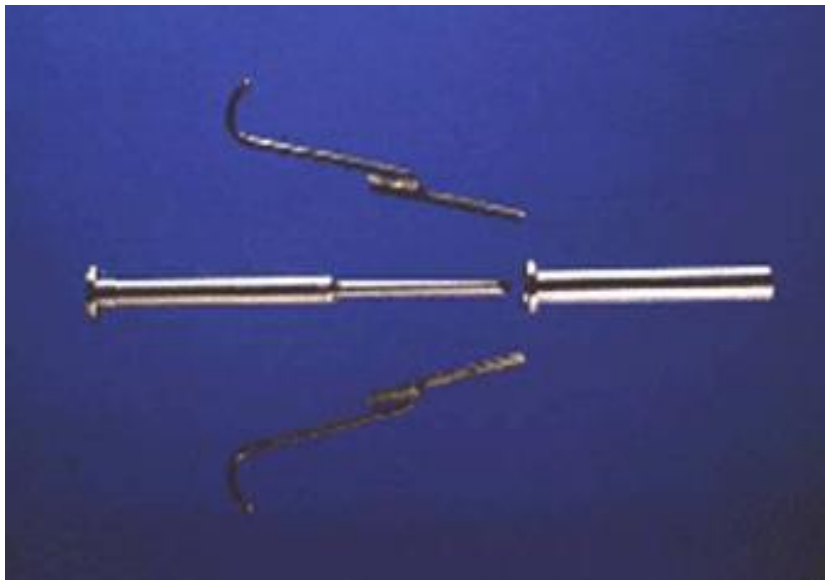
**Gold finger!!**

**Surgeon**
**Invasive Radiologist**
**Nephrologist**
**GP**
**Nurse**

# Different methods of catheter insertion

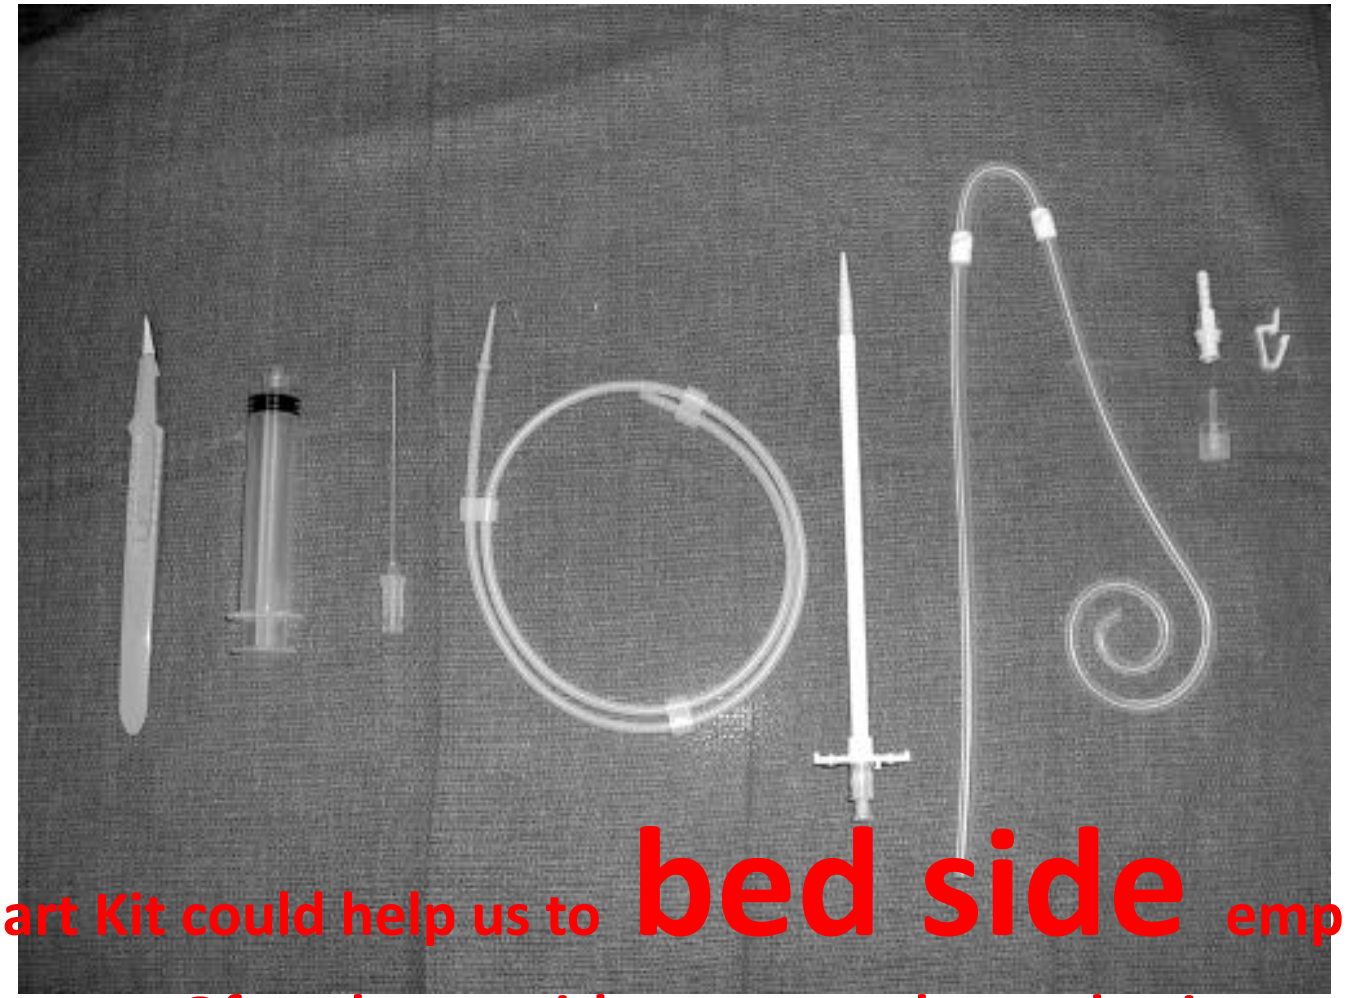
**Surgical**
**Laparoscopic**
**percutaneous**

# Using not a rigid instrument



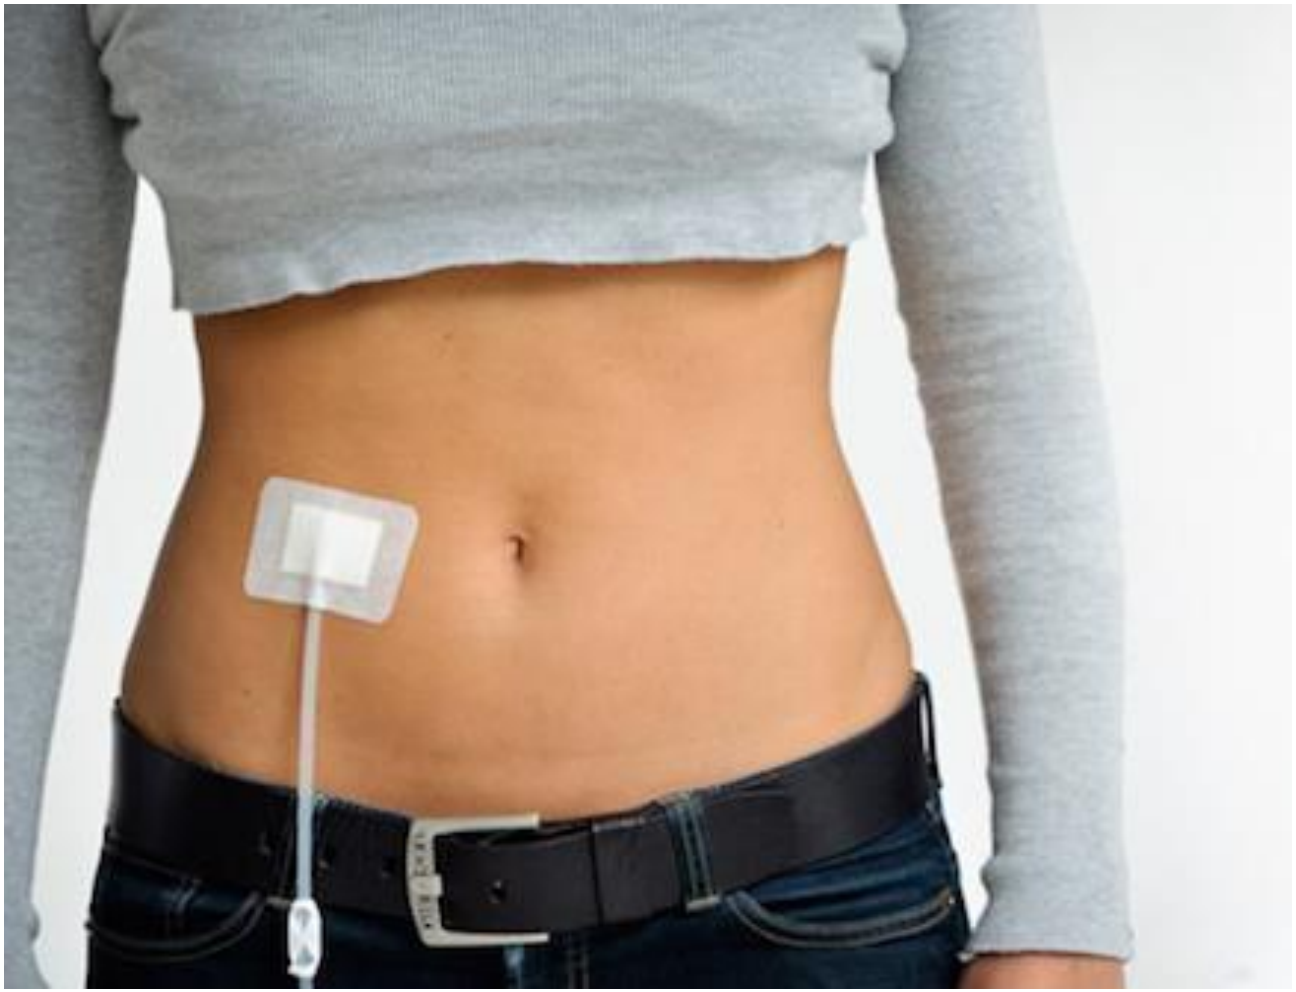
# It would be the consequences leak & …

Contents of the Quinton insertion kit: #11 scalpel, 10-cc syringe, 18-gauge introducer needle and 10-cc syringe, J/straight guidewire, 16-French **Pull-Apart introducer**, Swan neck curl cath, double-cuffed PD catheter, beta-cap adapter, cap, clamp

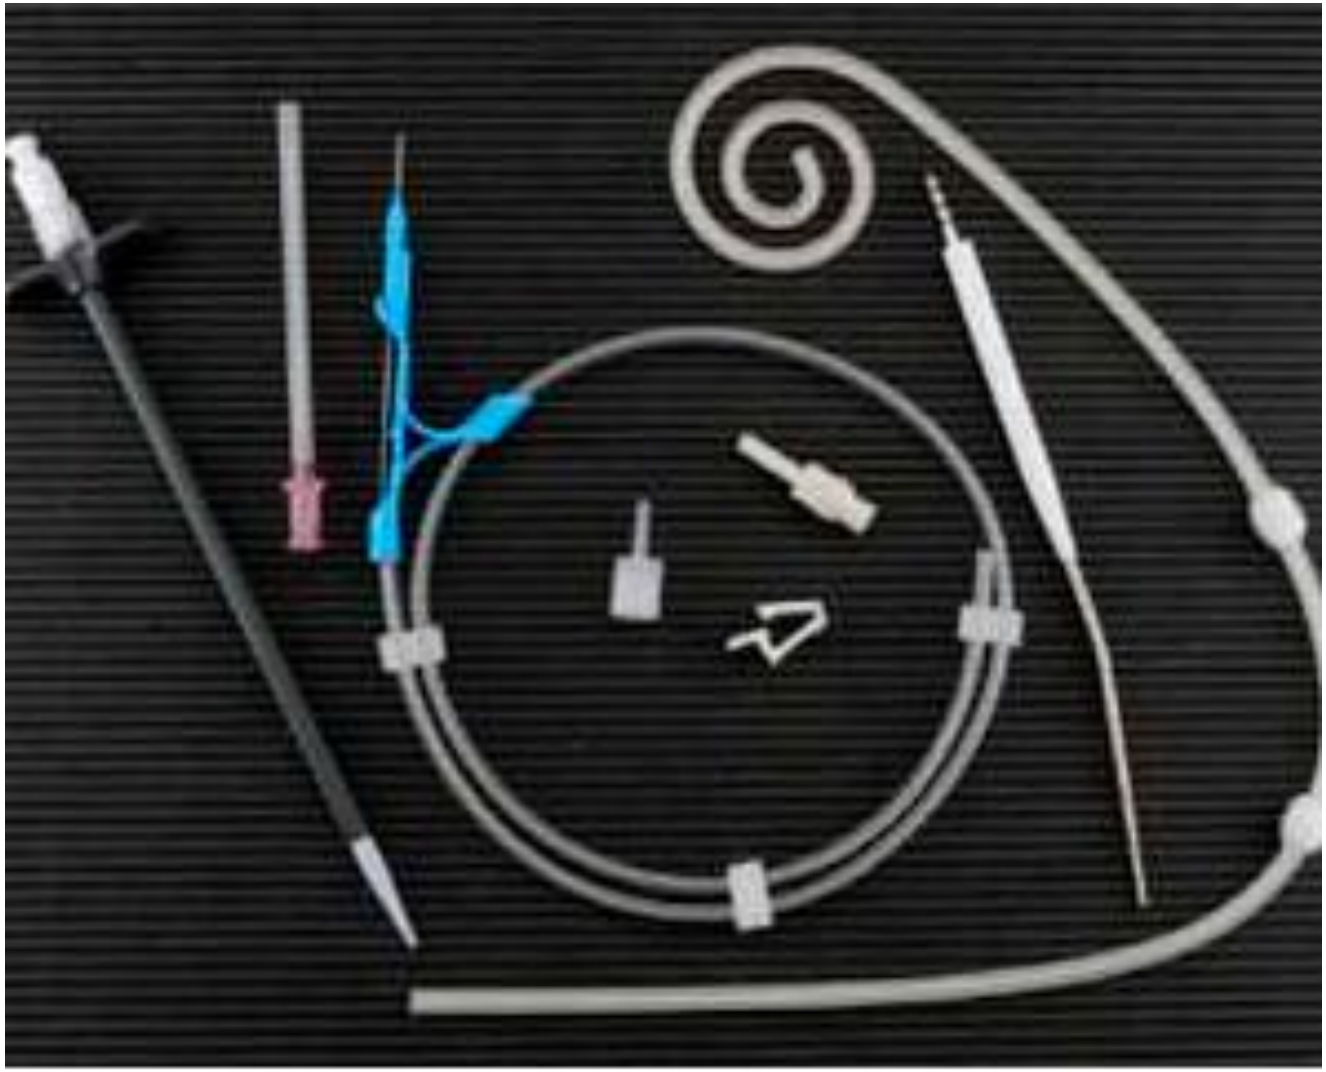


**Pull Apart Kit could help us to bed side emplacement Of catheter without general anesthesia**

# Gentle Insertion



# Gentle instrumentation



Recumbent
Low Volume
Intermitttent

# Urgent-start PD

# *Prescription*

3. PD modality: the U-s PD can be implemented through CAPD or APD but it is preferred to be in-center APD.
4. Fill volume: according to BSA of the patient
   - 500 ml if BSA < 1.65.
   - 750 ml if BSA 1.65-1.8.
   - 1000 ml if BSA > 1.8.
5. PD solution:
   - 1.5% dextrose if no peripheral edema or shortness of breath.
   - 2.5% dextrose if edema or shortness of breath.
   - 4.25% if prescribed by treating physician.

# Infectious and Mechanical Complications

| Complications | Urgent-Start PD (n=18) | Non-Urgent-Start PD (n=19) |
|---|---|---|
| No. of peritonitis episodes | 1 | 1 |
| Peritonitis rate (/patient-month) | 1/110 | 1/42 |
| No. of exit-site infections | 2 | 1 |
| Exit-site infection (/patient-month) | 1/55 | 1/42 |
| Minor leaks | 4 (22.2) | 1 (11.1) |
| Major leaks | 2 (11.1) | 0 (0) |
| Poor initial drain | 0 (0) | 1 (11.1) |
| Primary nonfunction | 2 (11.2) | 2 (22.2) |
| Hematoma | 1 (5.6) | 0 (0) |
| Bowel perforation | 0 (0) | 0 (0) |

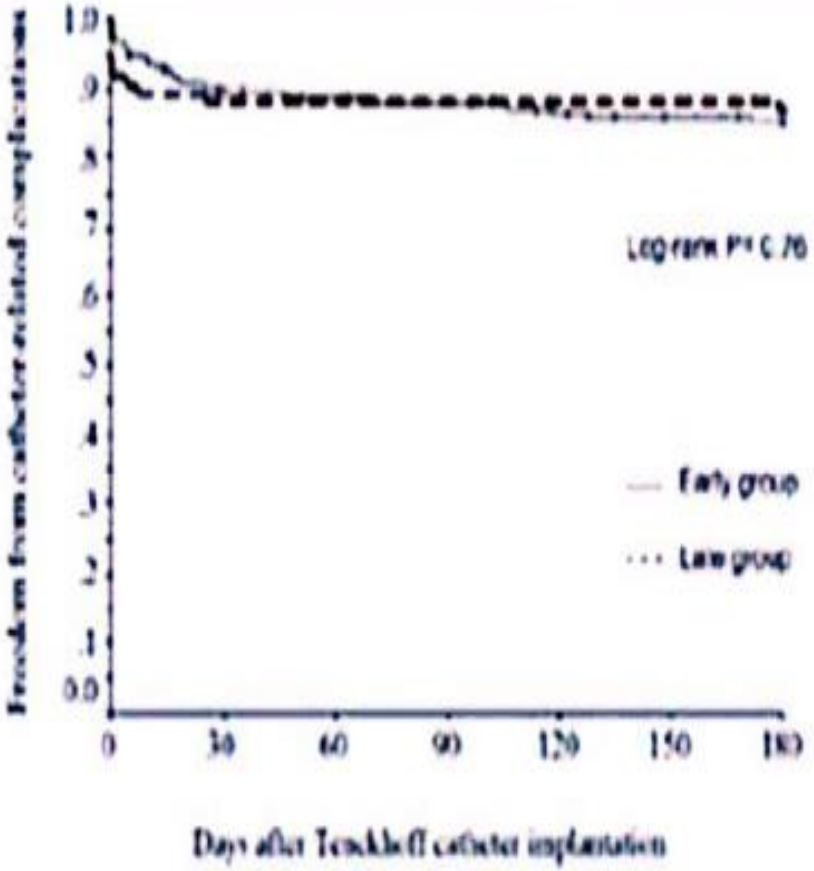


Figure 2 — Actuarial freedom from catheter-related complications is displayed using the Kaplan-Meier method. The early and late groups show no statistical difference with respect to overall catheter-related complications up to 6 months after starting CAPD (log rank $p = 0.76$). Early = break-in period ≤14 days; late = break-in period >14 days.

TABLE 2

Catheter-Related Complications Within Six Months

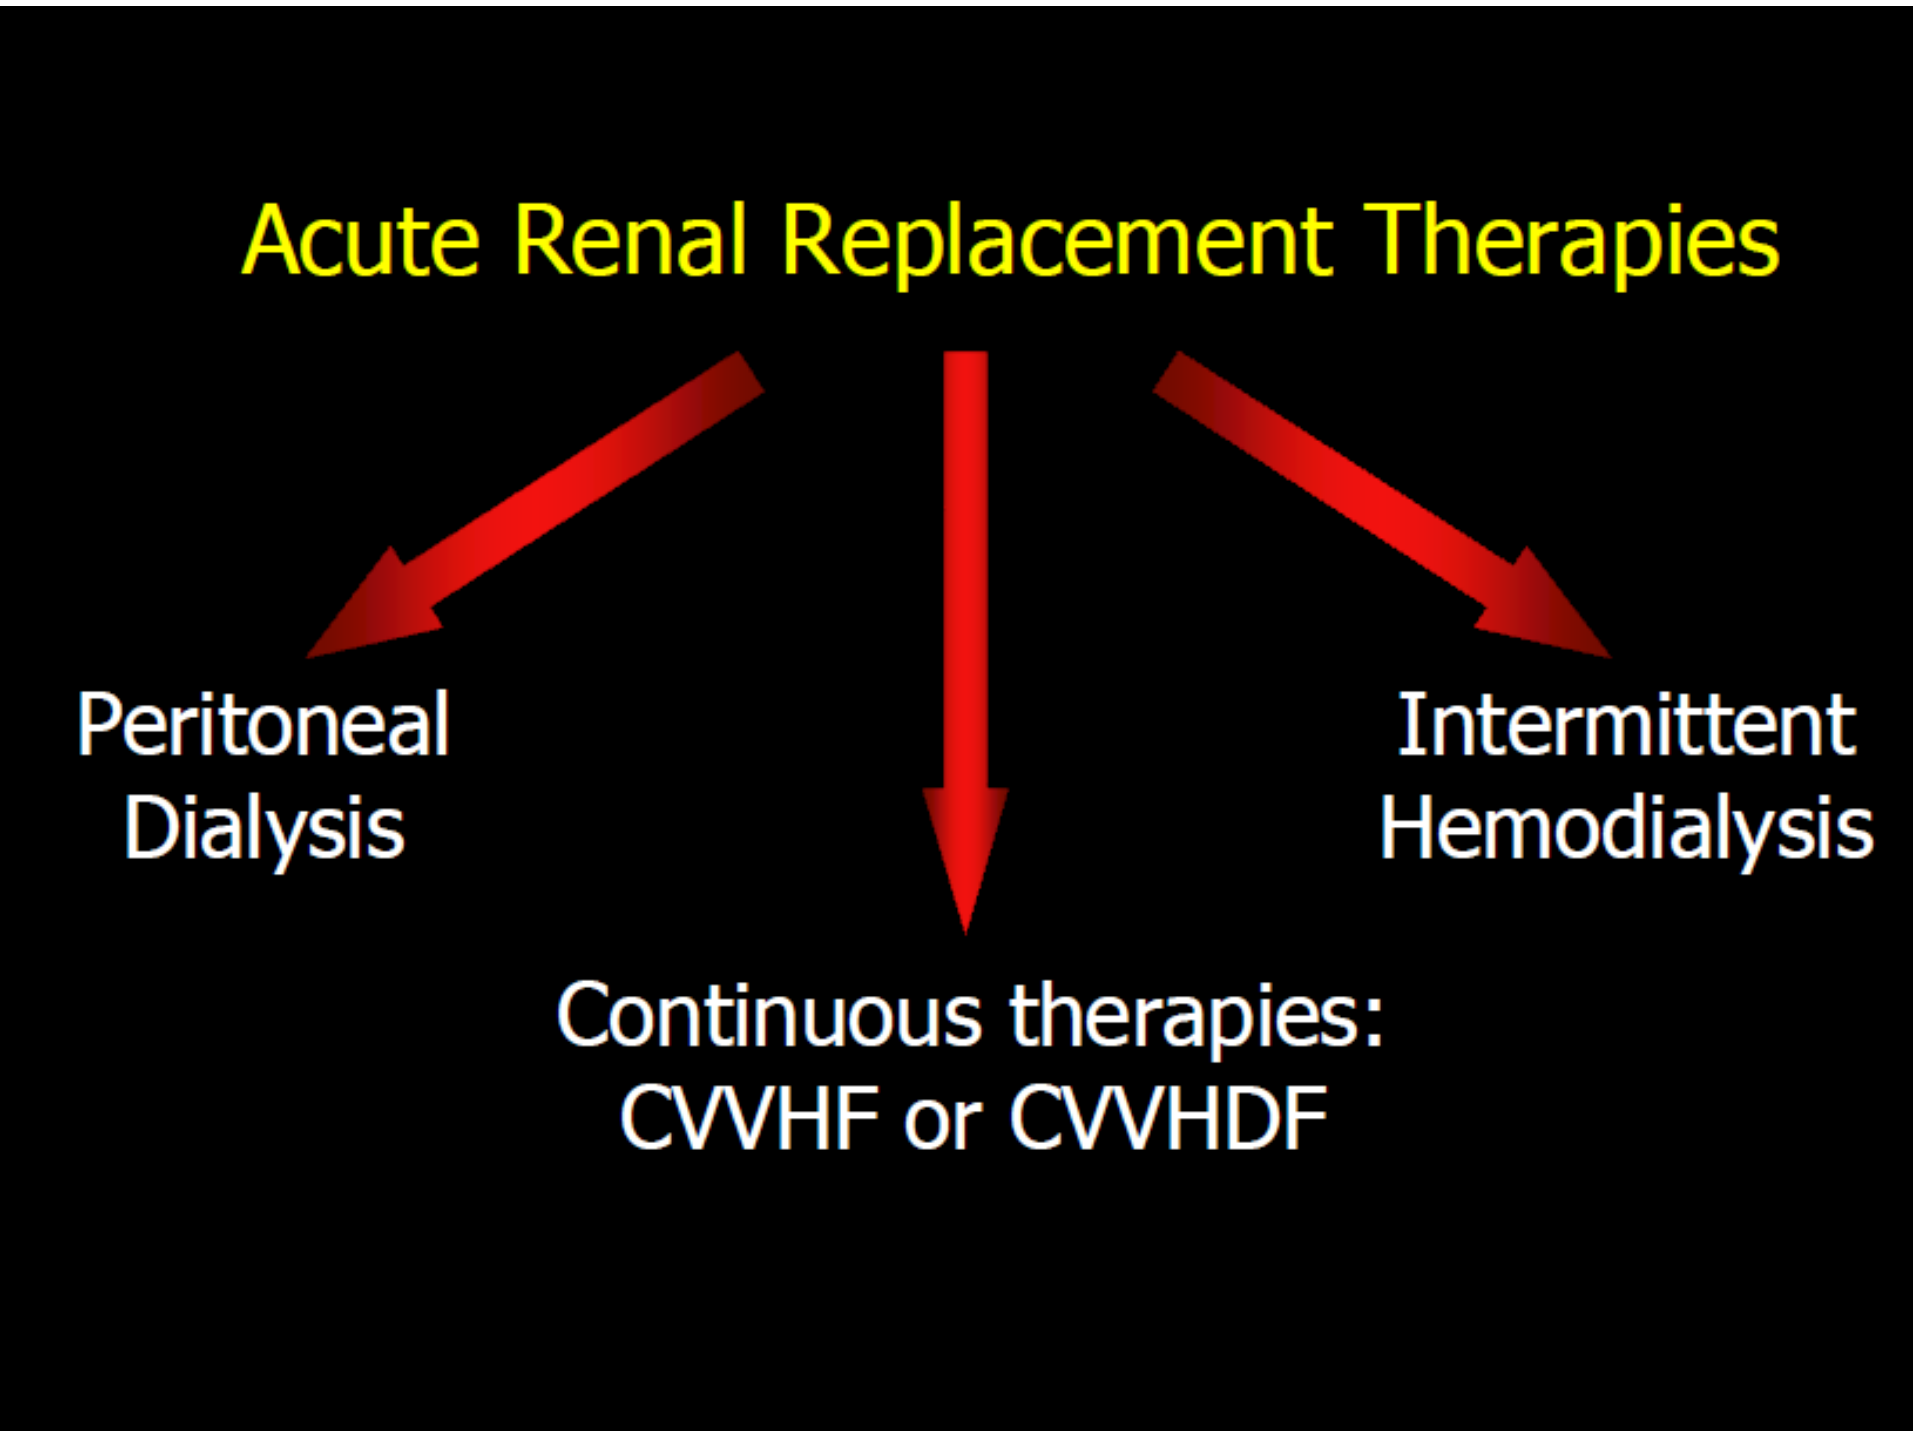
| | Early ($n$=226) | Late ($n$=84) | $p$ Value |
|---|---|---|---|
| Complication cases ($n$) | 33 (14.6%) | 11 (13.1%) | 0.74 |
| Mechanical complications | | | |
| Leakage | 5 (2.2%) | 2 (2.4%) | |
| Diminished outflow volume | 7 (3.1%) | 5 (6.0%) | |
| Migration | 7 (3.1%) | 2 (2.4%) | |
| Pericatheter hernia | 1 (0.4%) | 0 (0%) | |
| Hemoperitoneum | 1 (0.4%) | 0 (0%) | |
| Infectious complications | | | |
| Pericatheter infection | 3 (1.3%) | 0 (0%) | |
| Peritonitis | 9 (4.0%) | 2 (2.4%) | |

Early = break-in period ≤14 days; late = break-in period >14 days.

# AKI

❖ **The most important question in the management of ARF probably relate to:**

- Modality selection
- Dialysis dose
- Adequate start and stop
- Consequence on residual renal function



Acute Renal Replacement Therapies
Peritoneal Dialysis
Intermittent Hemodialysis
Continuous therapies:
CVVHF or CVVHDF

JAMA. 1959;170(8):917-924

# PERITONEAL DIALYSIS

## 1. TECHNIQUE AND APPLICATIONS

**PD ... the modality first used for the treatment of AKI**

eliminated by a new technique of intermittent dialysis utilizing commercially prepared electrolyte solutions, special catheters, and a "closed system" of infusion and drainage. This was mechanically successful in 76 instances. Conditions treated satisfactorily included acute renal failure, barbiturate poisoning, intractable edema, hepatic coma, hypercalcemia, and chronic uremia. Although less efficient than the artificial kidney on an hourly basis, peritoneal lavage is easier to use over extended periods of time.

# What Nephrologists do is not that they think!!!

In 2009 a survey by George

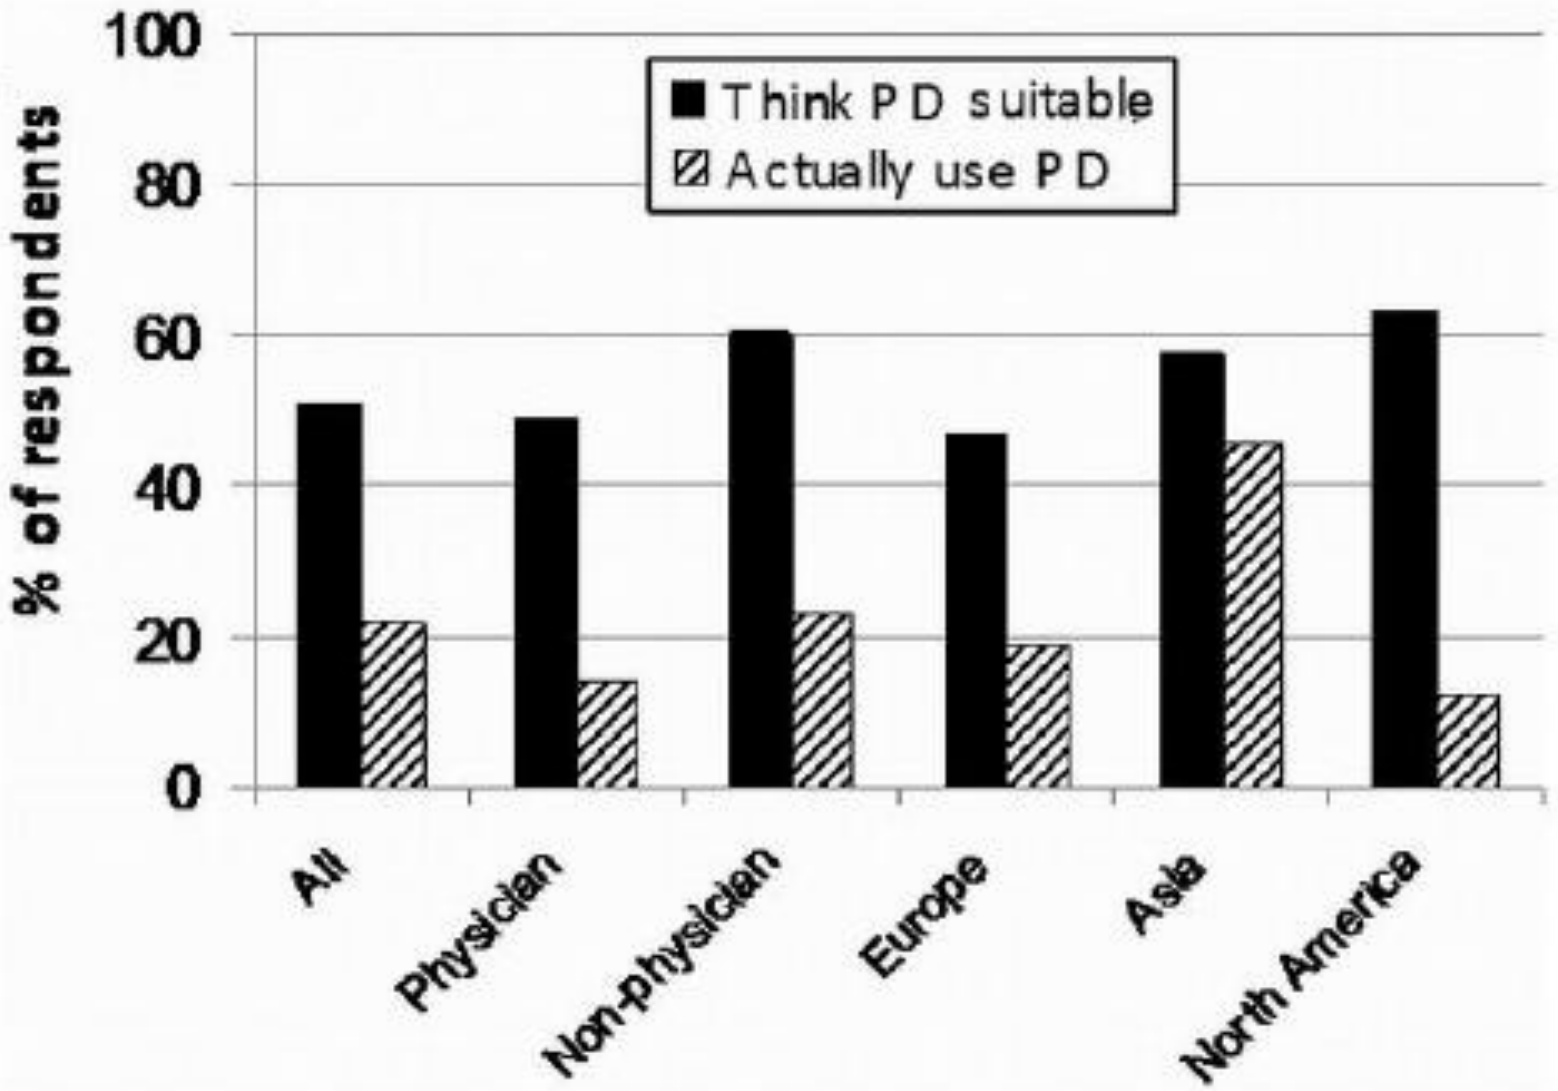
**55%** of the Nephrologists felt that PD was a suitable modality for AKI patients , but only **22%** were actually using the modality.!!!!1

PD was used in ~**46%** in Asia-Pacific/Australia regions and lesser in Europe**18.9** and North America, **12.2%**, respectively.

# Gaiao *et al.'s survey*

- Amongst delegates at 3 major dialysis congresses, found that
- **36%** felt PD was suitable for AKI in the intensive care unit **(ICU);** however, only
- **15%** actually practiced it

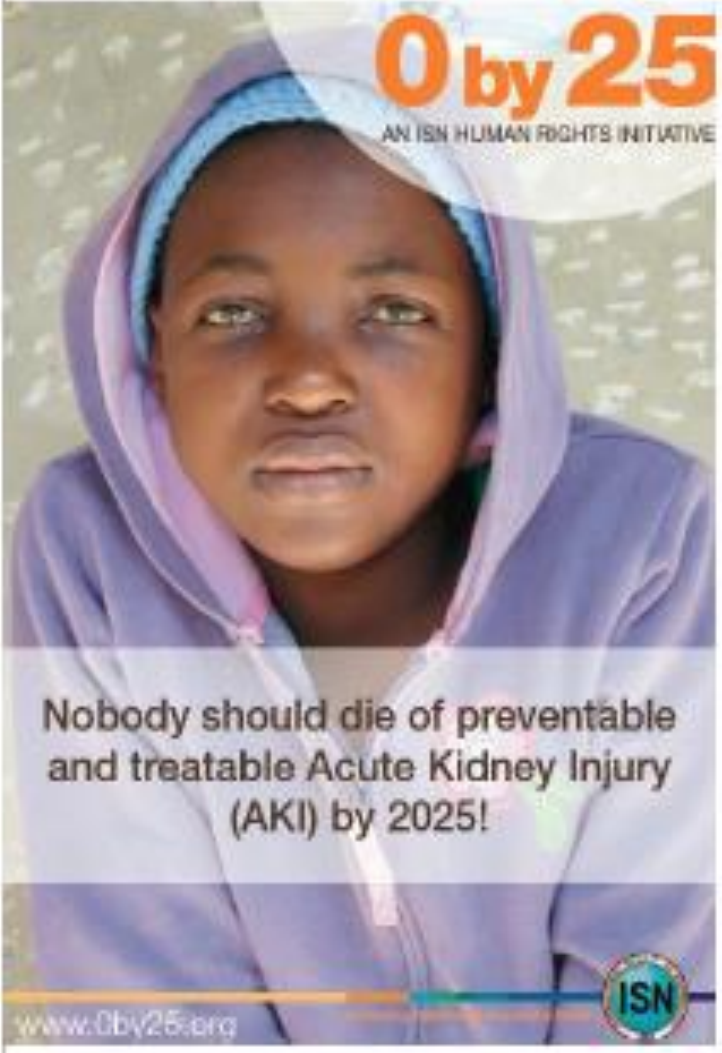
- When it came to treating AKI in the **wards,** more than **50%** felt it was suitable .



Gaiao S Perit Dial Int 2012

# EBP Vs PD in AKI

- Acute PD is practiced by **physicians from Asia** compared to those from Europe and North America
- **Cost** and available resources are major issues
- PD does not require **electricity** nor does it use **expensive machinery** or consumables
- George et al. noted that acute PD costs half that of hemofiltration



# Saving Young Lives

## IN AFRICA AND ASIA

*A partnership to deliver care for acute kidney injury in the developing world*

IPNA ISN SKCF

# Uchino *et al*

❖ **In a study involving 54 nephrology centers distributed over five countries.**

- **CVVH** were the major methods used in patients with ARF in almost **80%** of services, while **PD** was used in **3.2%** of these centers and intermittent **HD** in **16.8%** .

- In **Latin America**, particularly in Brazil, PD was used in **23%** of patients with ARF and in **Europe** in **21%** .

- **Peritoneal dialysis** for ARF still constitutes the mainstay of therapy in many **developing countries** .

# EBP Vs PD in AKI

- Furthermore, PD use to treat AKI is limited to small children in many countries, especially in **Western countries.**

- Contributing factors include the development of efficient and easy-to-place **central venous catheters**

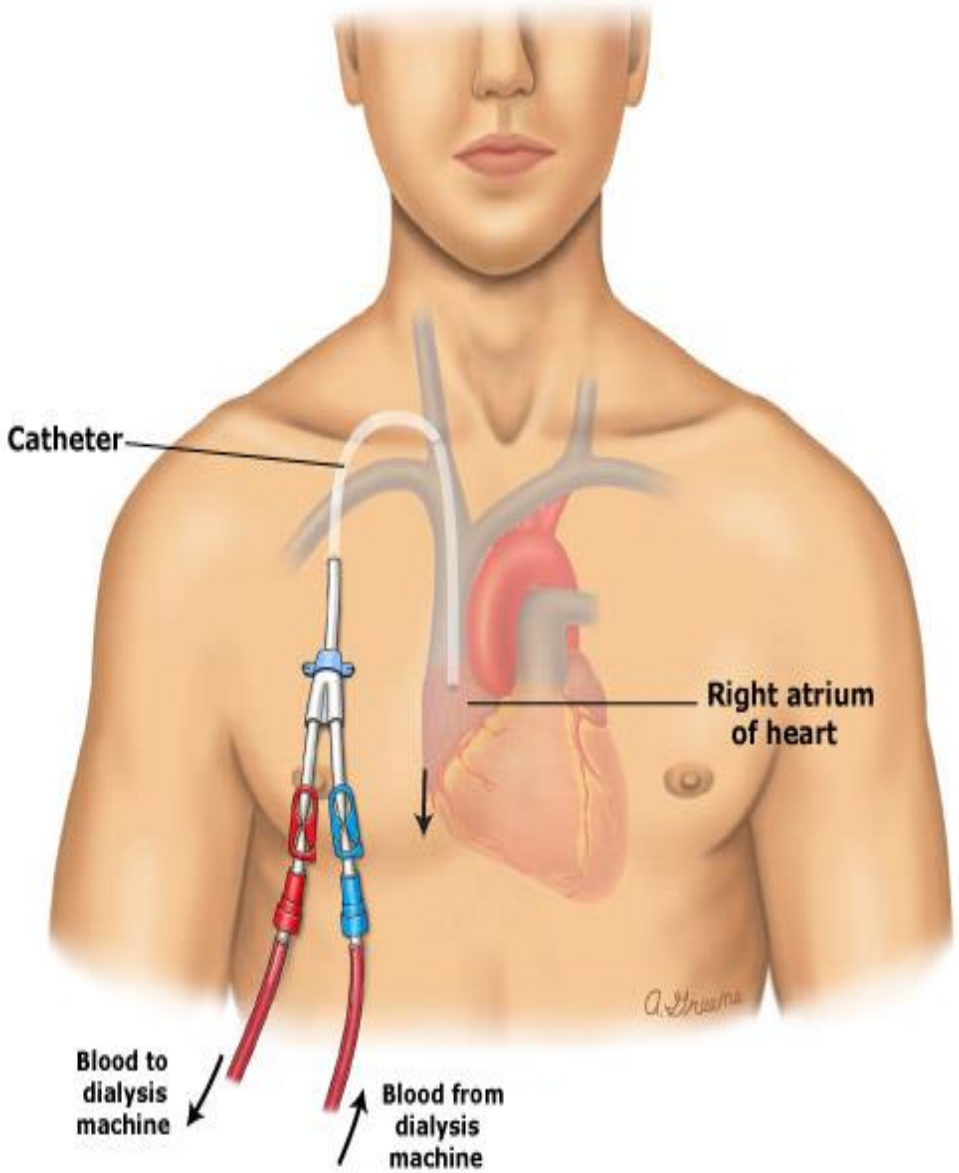
- The expanded use of **CRRTs** and slow extended daily dialysis in these countries

- The perception that PD offers **inferior care**

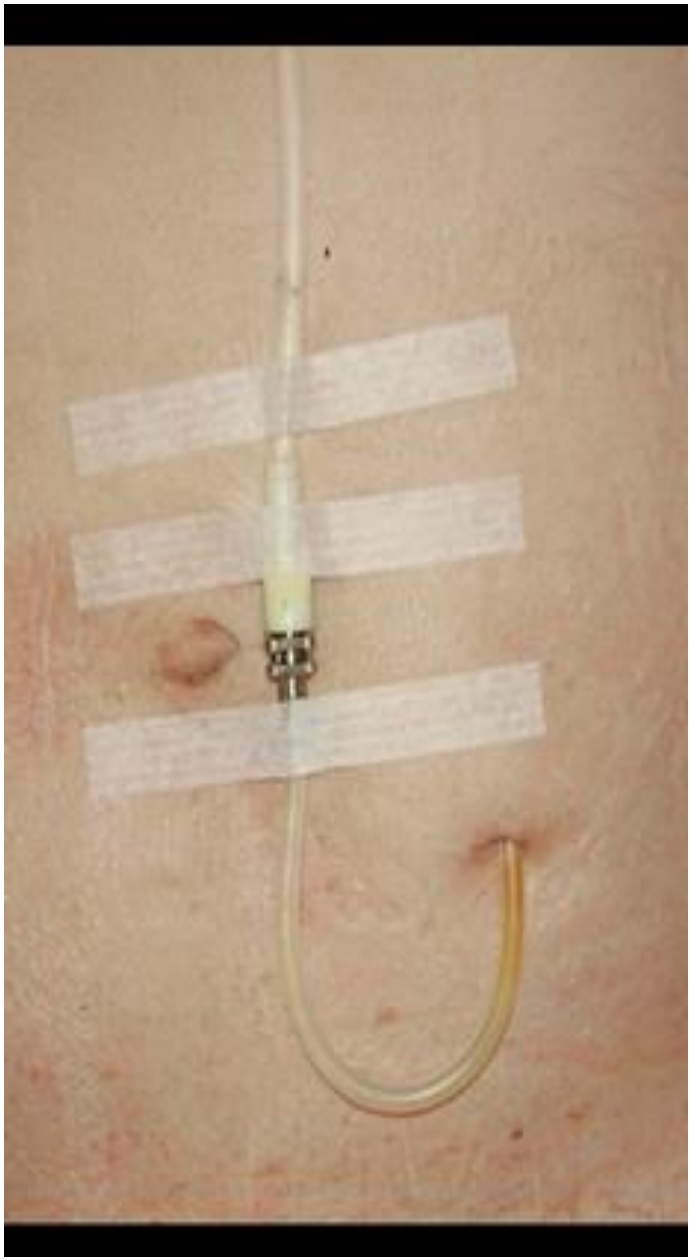
A-V SHUNT (LEFT ARM)

**Figure 3. An AV shunt in the ankle, a popular procedure with the PMH team.**

**Figure 2. An infected AV shunt.**

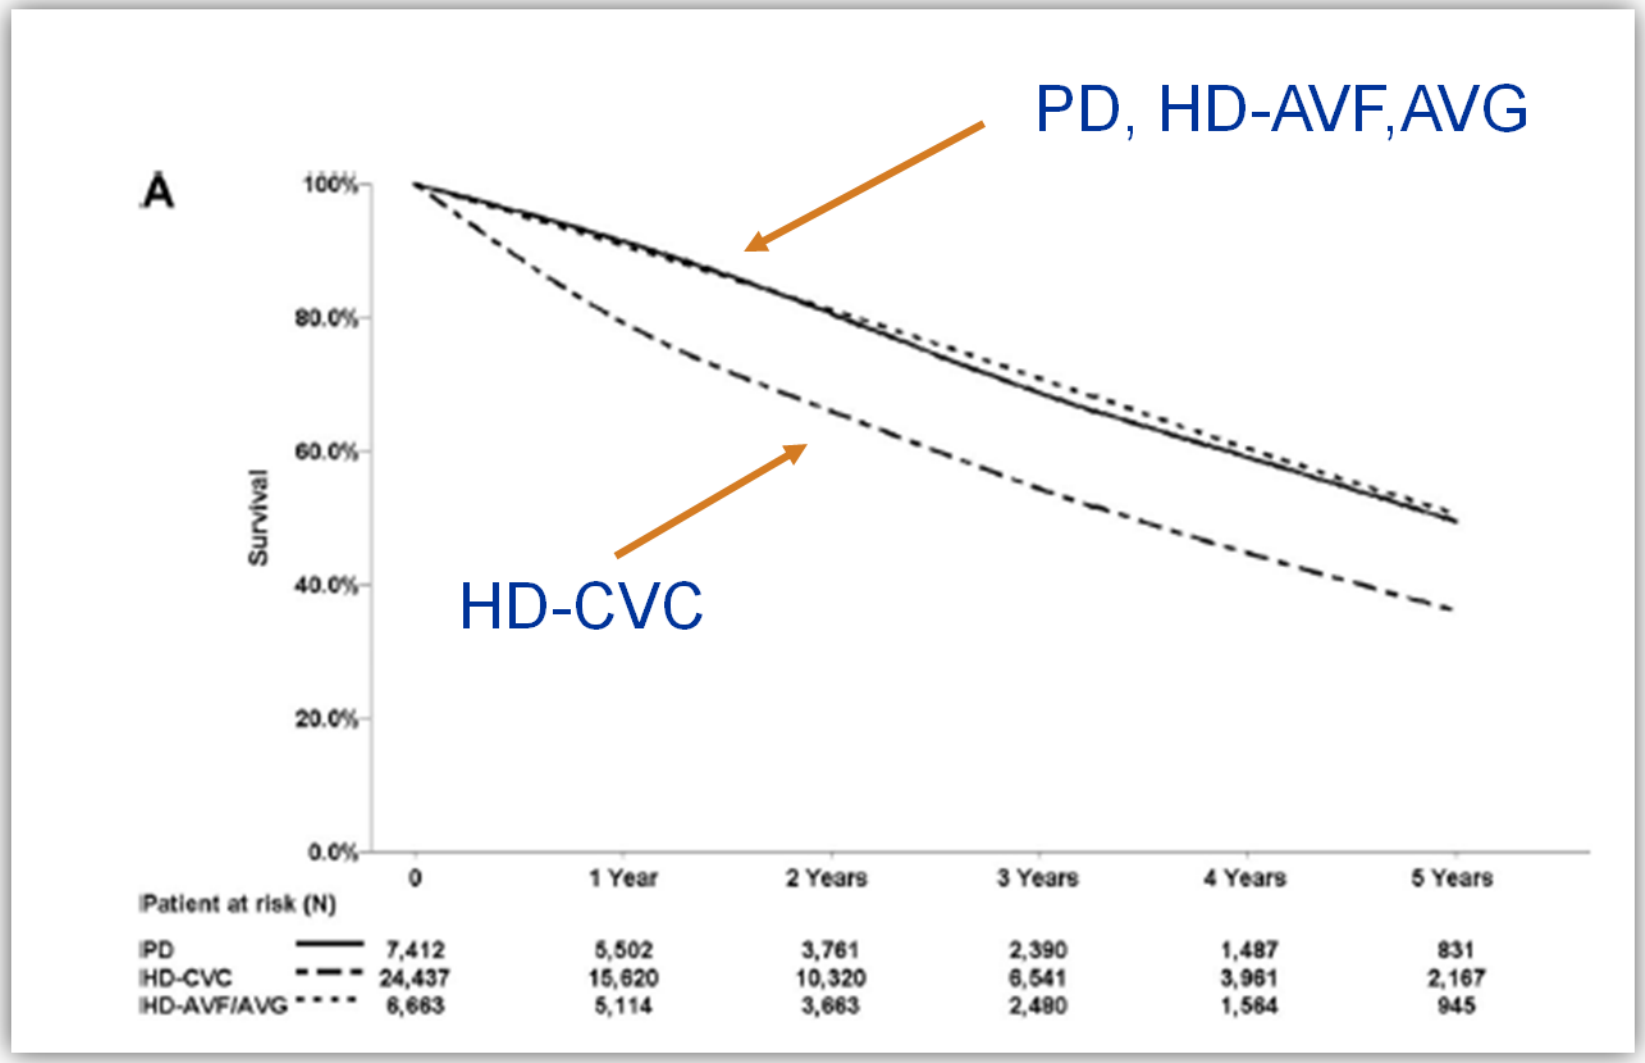


**But when this came to market PD lost its patients and loose the game to HD**



# Survival Curves by Modality and Access Type

Perl J et al. J Am Soc Nephrol 2011;22:1113-1121.



# EBP Vs PD in AKI

- When comparing the **overall risk of each type** of therapy for ARF, there are marked differences between CVVH, CVVHD, HD and PD.

- The **blood treatment** therapies have a significant risk of septicemia, low flow from blood access, hypotension, membrane clothing and bleeding.

- **PD** therapy includes risk of PD catheter outflow failure, leak, hyperglycemia and asymptomatic peritonitis.

# Developing vs Developed countries

The etiology of AKI varies in developed and emerging economies

**Much more Hypercatabolic**

**In western countries**

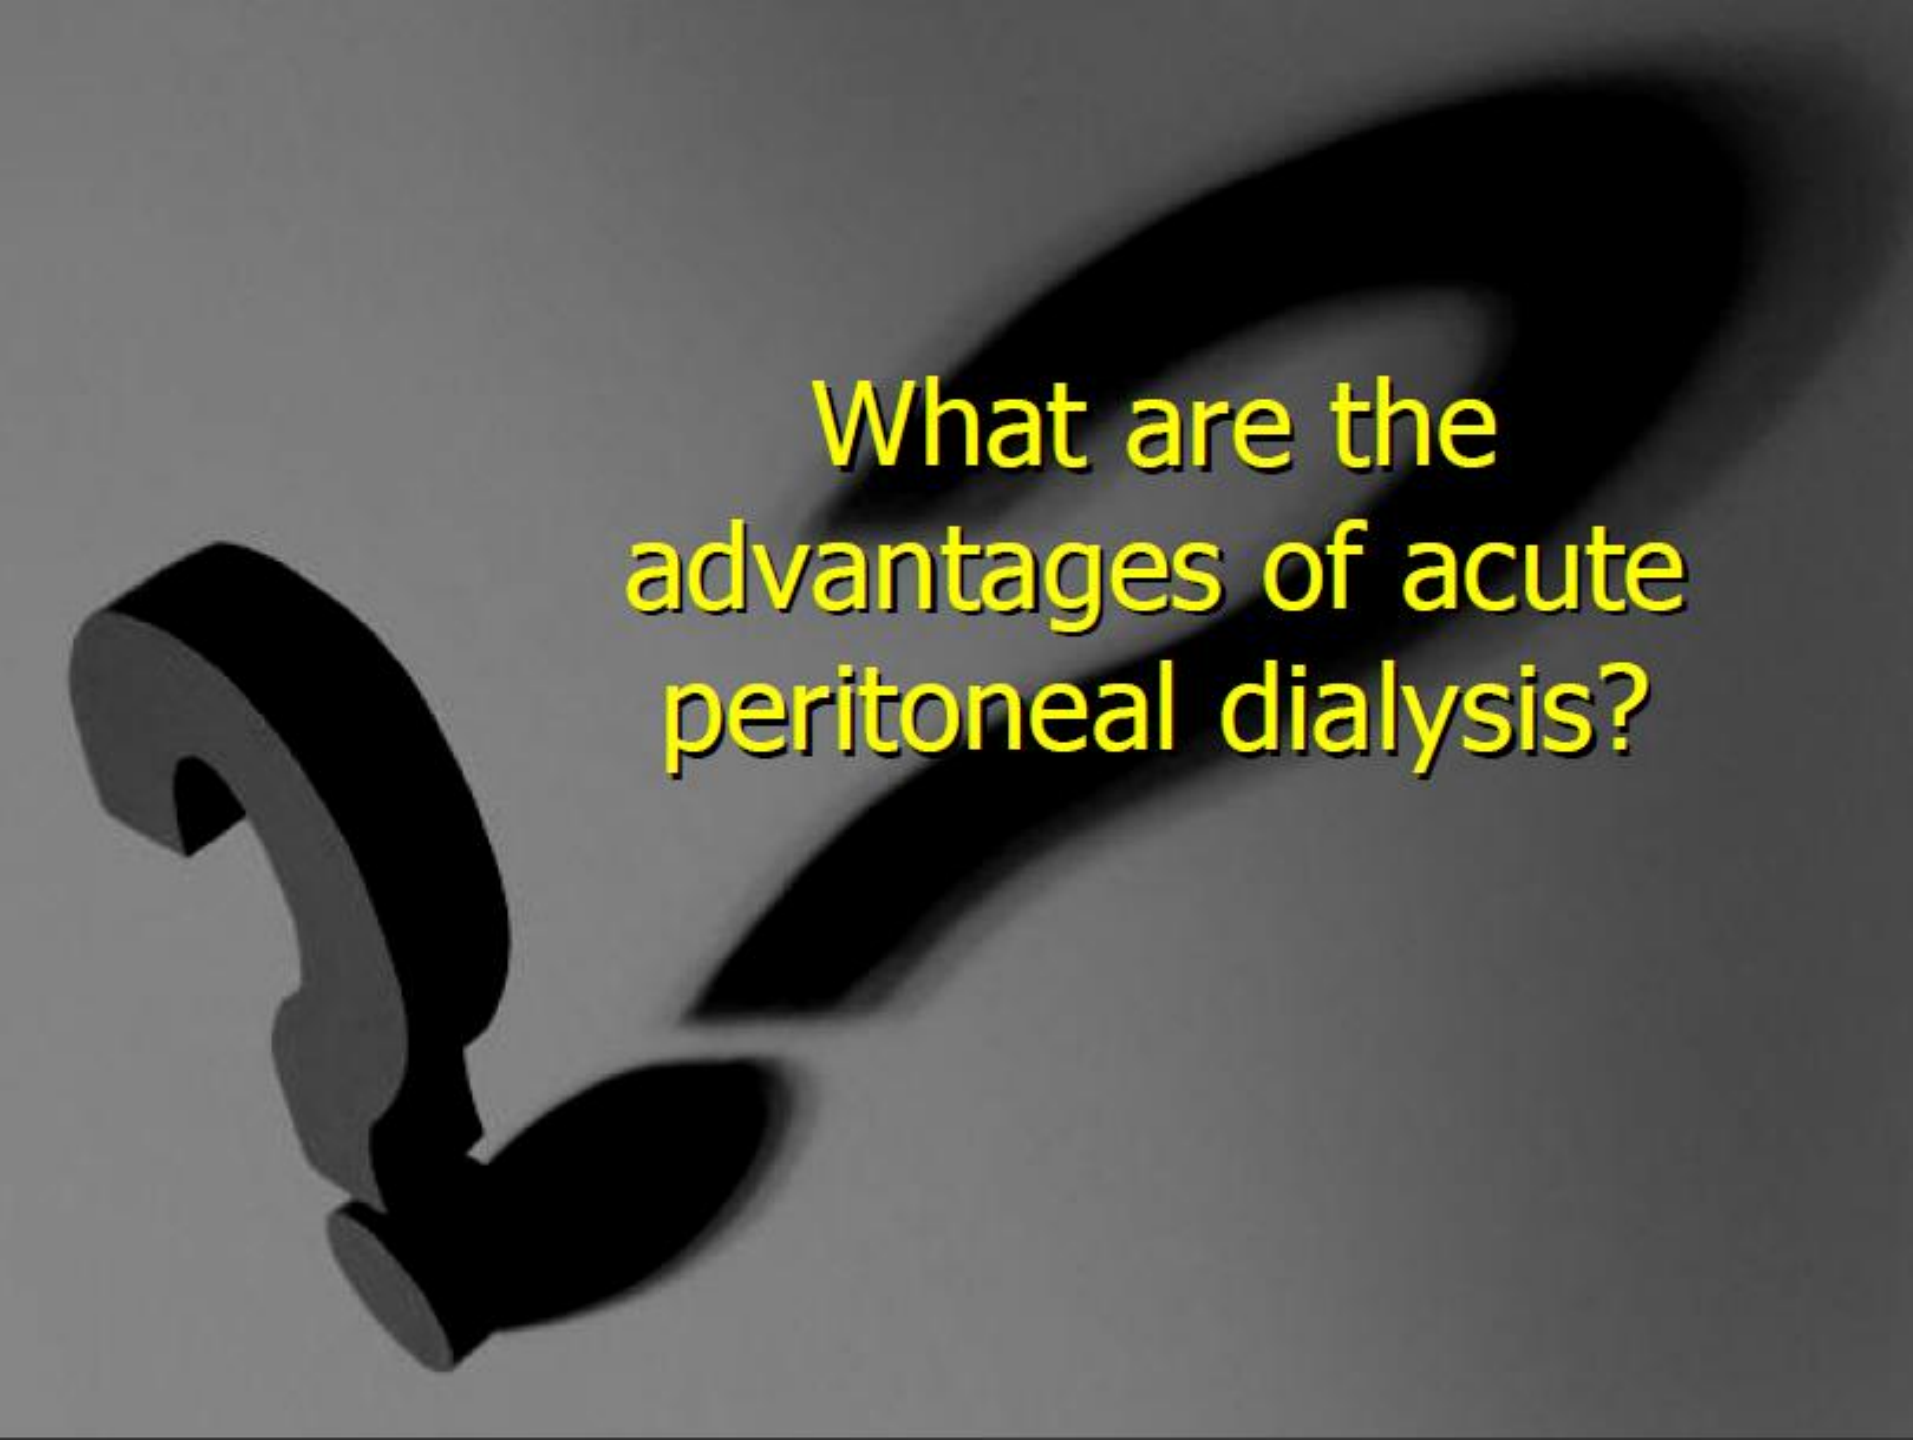
# Comparison of AKI

| 'Developing' Countries | 'Developed' Countries |
| --- | --- |
| • Infections and poisoning | • Sepsis (primary/secondary) |
| • Underlying HIV | • Underlying Diabetes |
| • Younger | • Older |
| • Pre-existing normal function | • Often Acute on Chronic |
| • Single organ failure | • Multimorbidity |
| • Logistics favour PD | • Logistics favour HD/CVVHD |
| • Recovery good | • Recovery limited |
| • CKD later | • Remain dialysis dependent |

# PD for ARF

**Table 1.** Indications and relative contraindications for peritoneal dialysis in patients with acute renal failure

| Indications for acute peritoneal dialysis | Relative contraindication for acute peritoneal dialysis |
|---|---|
| Hemodynamically unstable patients | Recent abdominal or cardiothoracic surgery |
| Bleeding diathesis or active hemorrhage | Diaphragmatic pleuroperitoneal connections |
| Problem with vascular access | Fecal or fungal peritonitis |
| Pediatric ICU | Severe respiratory failure |
| Atheroembolic renal disease? | Abdominal wall celulitis |
| ARF due to malignant hypertension? | Severe reflux disease |
| Unavailability of other continuous therapies | Extremely high catabolic status with hyperK |
| Special circumstances (disasters) | Pulmonary edema |
| | Peritoneal adhesions |



What are the advantages of acute peritoneal dialysis?

# Why PD for AKI?

- Simple technology – no requirement for continuous external power, complex monitoring systems
- Cost effective – life saved ~ $350
- Effective (metabolic acidosis, electrolytes, UF – including high volume regimes for hyper-catabolic)
- Preferred method: infants, children, head injuries, encephalopathy, post-cardiac surgery, cardiac failure (e.g. CHF with acute reversible decompensation), anti-coagulation difficulties, ascites

Next slide

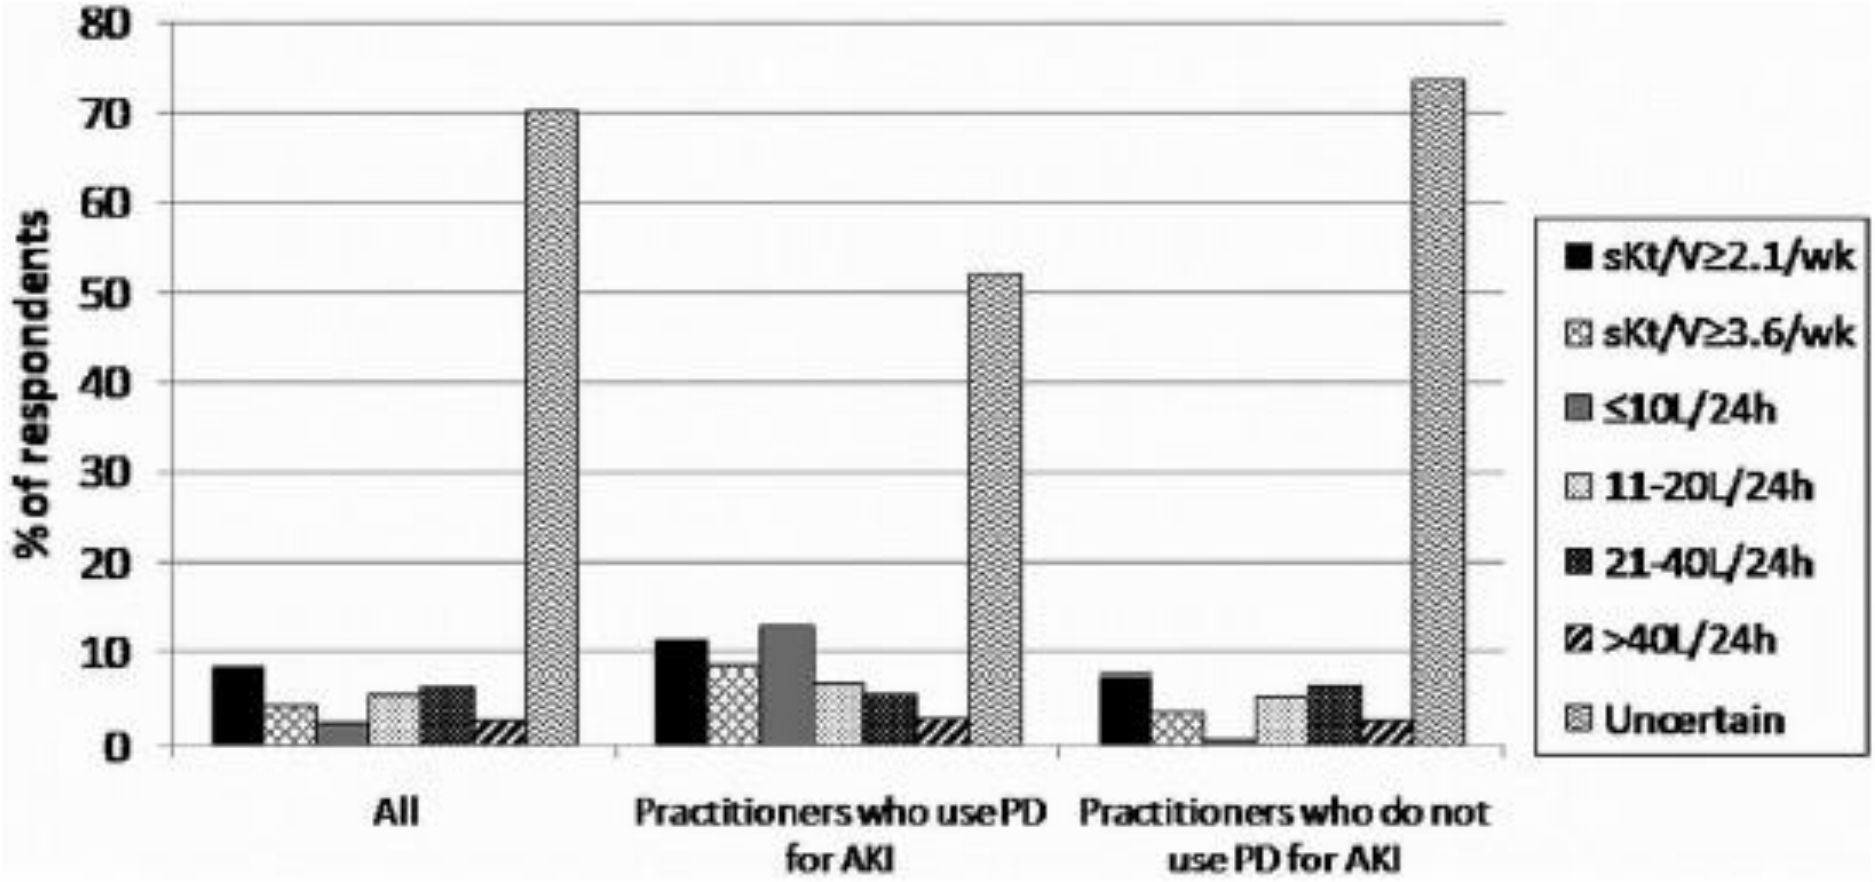
# Gaiao *et al.'s survey*
# PD dose

- Indeed, **66 – 70%** of practitioners professed uncertainty regarding the appropriate PD dose.

- Even among those who did use PD for AKI, **37 – 52%** were uncertain of the appropriate dose

- In published studies, weekly Kt/V's have ranged between **1.8** and **5.6** and fluid volumes have varied from **13 – 70 L** per day

- This is likely related, at least in part, to a lack of definitive data and/or consensus guidelines.



Gaiao S Perit Dial Int 2012

# Dose of PD in ARF

- We know that hyperkalemia, acidosis, and massive fluid overload need to be treated first.

- Then the dose and importance of removal of small molecules or larger molecule clearances should be addressed.

# Dose of PD in ARF

- **Weekly urea clearances**
  - Kt/V of 2.1 ‘minimum’ dose
  - Kt/V of 3.43 ‘maximum’ dose
  - Kt/V of 4.13 no extra benefit

  - Higher small-solute clearances may be necessary for those patients with more complex septic and catabolic illnesses

# Different PD regimen in ARF

**Table 2.** Techniques of peritoneal dialysis for ARF treatment

| Technique | Description |
|---|---|
| Acute Intermittent Peritoneal Dialysis (AIPD) | Most often used in the past. Frequent and short exchanges with volumes 1-2 liters and dialysate flows of 2-6 liters/h. Each session lasts 16-20 h, usually tri session per week. The solute clearance is likely inadequate due to its intermittent nature |
| Chronic Equilibrated Peritoneal Dialysis (CEPD) | Long dwells of 2-6 h with up to 2 liters of dialysate each (similar to CAPD). The clearance of small molecules may be also inadequate but clearance of middle molecules is possibly higher due to the long dwells |
| Tidal Peritoneal Dialysis (TPD) | Typically involves an initial infusion of 3 liters of dialysate into the peritoneal cavity. A portion of dialysate, tidal drain volume (usually 1-1.5 liters) is drained and replaced with fresh dialysate (tidal fill volume)The reserve volume always remains in the peritoneal cavity throughout the tidal cycle |
| High Volume Peritoneal Dialysis (HVPD) | Continuous therapy proposed to increase high small solute clearances. Frequent exchanges, usually with cycler (18-48 exchanges per 24 h, 2 liters per exchange). The total dialysate volume range from 36-70 liters a day |
| Continuous Flow Peritoneal Dialysis (CFPD) | In-flow and out-flow of dialysate occurs simultaneously through two access routes. By inflow of 300 ml/min it is possible to achieve a high peritoneal urea clearance |

# The dose of dialysis in AKI

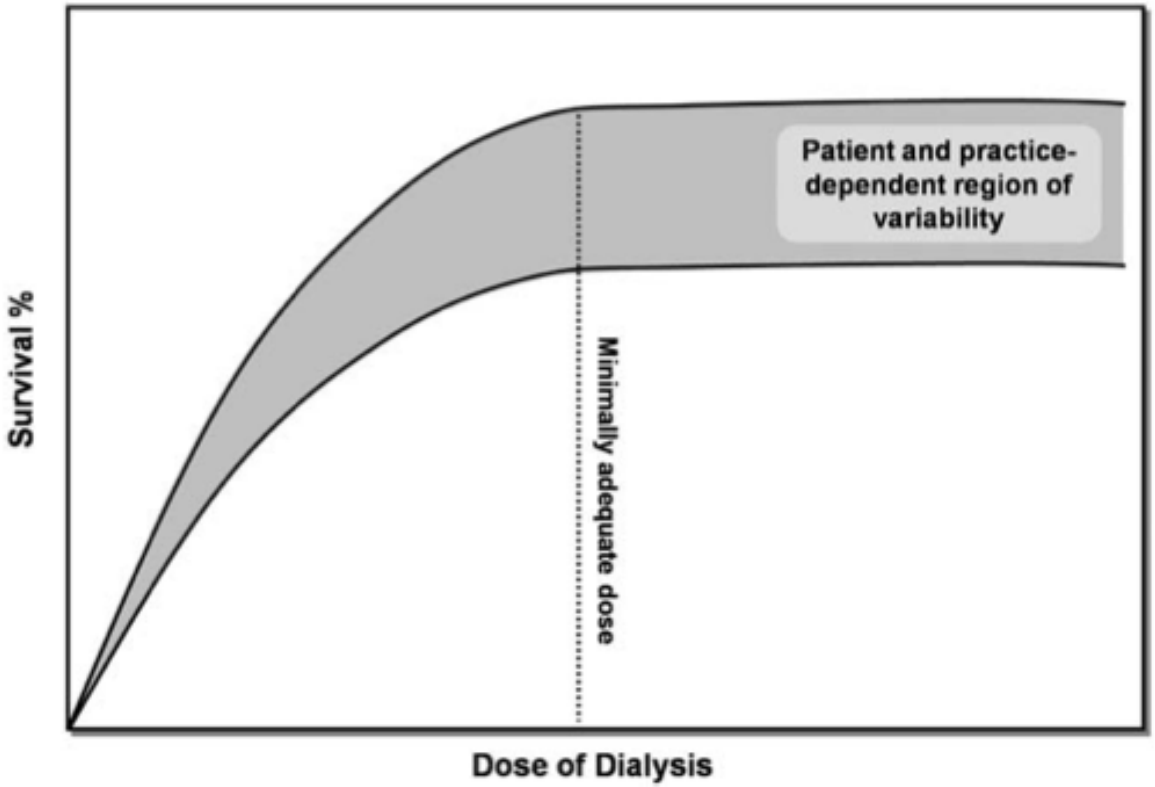

**Fig. 1.** The putative dose–response relationship between dialysis dose and survival (adapted from Ricci [26]). In uraemic patients who receive no dialysis, mortality is close to 100%. The probability of survival improves with dialysis. At low doses of dialysis, increasing the dosage improves survival, but this effect eventually tapers off. Beyond a certain threshold, further increments in dialysis dose will not reap further survival benefits.

# Dialysis Dosage & pts survival

By no dialysis, mortality is close to 100%.

Increasing dosage improves survival

Beyond a certain threshold, increments in dialysis dose will not improve patients survival

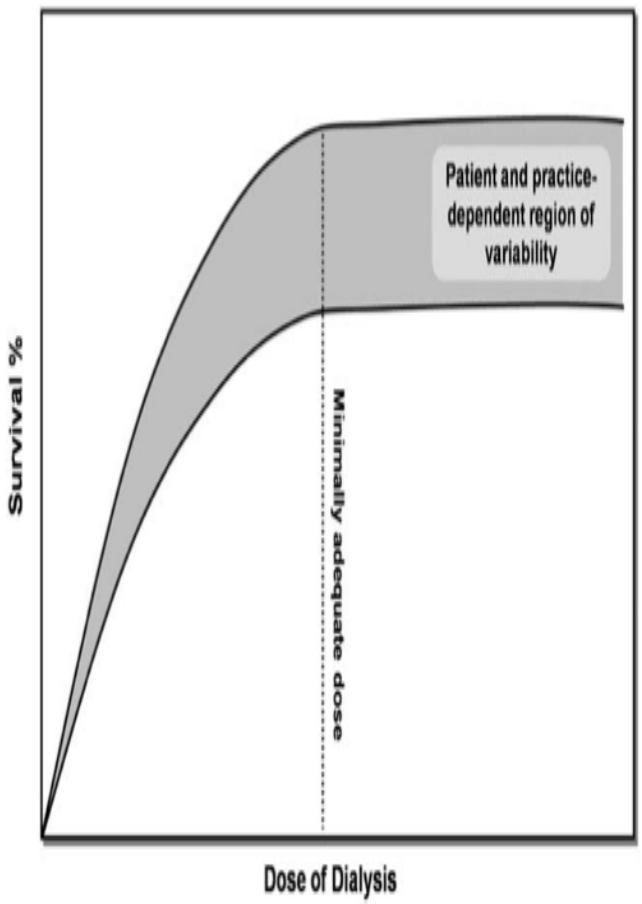

**Fig. 1.** The putative dose–response relationship between dialysis dose and survival (adapted from Ricci [26]). In uraemic patients who receive no dialysis, mortality is close to 100%. The probability of survival improves with dialysis. At low doses of dialysis, increasing the dosage improves survival, but this effect eventually tapers off. Beyond a certain threshold, further increments in dialysis dose will not reap further survival benefits.

# Is PD adequate in acutely ill ARF patients

- Most of the studies that have evaluated PD in hypercatabolic ARF reported **PD** as having **adequate** and satisfactory **control of fluid and metabolic derangements.**

- **However, they have major limitations**
  - small sample sizes,
  - inadequate measurement of catabolic status,
  - lack of apropriate measurements of dialysis adequacy

# Is peritoneal dialysis adequate for hypercatabolic acute renal failure in developing countries?

**VIPUL CHIMANLAL CHITALIA, ALAN FERNANDES ALMEIDA, HARINAKSHI RAI, MANSI BAPAT, KINNARI VIPUL CHITALIA, VIDYA N. ACHARYA, and RAMESH KHANNA**

*Division of Nephrology, Department of Medicine, Renal Laboratory, and Department of Dietetics, Seth G.S. Medical College & King Edward Memorial Hospital, University of Bombay, Mumbai, India; Department of Dietetics, University of New Haven, Yale School of Medicine, New Haven, Connecticut, and Division of Nephrology, Department of Medicine, University of Missouri Health Science Center, Missouri, St. Louis, USA*

**Conclusion：**

**TPD** produced higher solute clearances in less time with greater protein loss.

**CEPD** just fell short to meet dialysis adequacy standard.

However, both **TPD** and **CEPD** are reasonable options for mild-moderate hypercatabolic ARF.

**Kt/V** appropriately estimates solute removal in PD.

# Hypercathatabolic renal failure

- Patients were **grouped into mild, moderate and severe hypercatabolic** according to the severity of catabolism as estimated by the excess urea appearance rate (UNA) (vide infra)

- **Patients with mild-moderate hypercatabolic ARF** (excess UNA, above the dietary nitrogen intake up to 12 g/day) **were randomized in the trial.**

# Hypercathatabolic renal failure

- **Patients with any of the following conditions were excluded:**
- Inadequate instability (systolic blood pressure < 80 mm Hg)
- Pulmonary edema
- Severe metabolic acidosis (blood pH <7.2 and plasma bicarbonate <14)
- Excess UNA more than 12 g/day (severe hypercatabolic renal failure)

# Criteria for effectiveness!

## Weekly Kt/V > 2 and Creatinine clearances > 60

**Table 4.** Pre- and post-dialysis BUN and creatinine, solute clearances (Kt/V, normalized creatinine clearances and solute removal indices) and ultrafiltrate in TPD and CEPD

| | TPD | | CEPD | | |
|---|---|---|---|---|---|
| Variables | Mean ± SD | Range | Mean ± SD | Range | *P* value |
| Pre-dialysis BUN *mg/dL* | 78.80 ± 8.30 | 68–125 | 77.96 ± 22.10 | 63–118 | 0.67 |
| Post-dialysis BUN *mg/dL* | 50.84 ± 11.30 | 42–68 | 64.71 ± 12.4 | 59–82 | 0.04 |
| Pre-dialysis creatinine *mg/dL* | 8.16 ± 2.73 | 4.9–10.30 | 7.79 ± 2.49 | 4–9.70 | 0.62 |
| Post-dialysis creatinine *mg/dL* | 5.01 ± 1.9 | 4.2–7.90 | 6.52 ± 1.61 | 4.60–8 | 0.02 |
| $C_{cl}$ *mL/min* | 9.94 ± 2.93 | 7.14–20.92 | 6.74 ± 1.63 | 3.94–9.34 | 0.01 |
| *L/session/1.73 m²* | 9.79 ± 1.13 | 6.94–11.34 | 7.40 ± 1.21[a] | 5.53–9.79 | 0.031 |
| *L/week/1.73 m²* | 68.5 ± 4.43 | 49.60–73.36 | 58.85 ± 2.57 | 43.73–68.49 | 0.035 |
| $C_{ur}$ *mL/min* | 19.85 ± 1.95 | 15.67–23.01 | 10.63 ± 2.62 | 8.38–12.52 | 0.001 |
| Kt/V (session) | 0.34 ± 0.14 | 0.18–0.50 | 0.26 ± 0.07[a] | 0.12–0.39 | 0.001 |
| Kt/V (week) | 2.43 ± 0.87 | 1.11–3.49 | 1.80 ± 0.32 | 1.47–2.75 | 0.001 |
| $SRI_{Dialysate}$ | 28.46 ± 4.6% | 41–57.9% | 20.64 ± 5.93% | 14–36.45% | 0.02 |
| $SRI_{Kt/V}$ | 21.06 ± 4.03% | 15.62–30.48% | 15.53 ± 5.45% | 9.5–21.47% | 0.02 |
| UF *ml/min* | 4.28 ± 0.70 | 3.01–5.8 | 1.82 ± 0.13 | 0.80–2 | 0.04 |
| *L/session* | 2.88 ± 0.71 | 1.89–4.14 | 2.01 ± 0.28[a] | 0.38–2.44 | 0.03 |

The difference was considered statistically significant by paired *t* test for $P < 0.05$ for $N = 87$. $C_{ur}$ is dialysate urea.

[a] Values of CEPD tabulated for 24 hours for comparison

# Comparing PD with dHD

- Observational comparative cohort study:
- 120 patients with ATN assigned to PD or dHD
- Age 63, men 75%, sepsis 45%, shock 62%
- Similar metabolic control
- Survival: PD 58%, dHD 52%
- Recovery of renal function: PD 28%, dHD 22%

Gabriel DP, KI 2008;73:587-593

# Comparing PD with CVVHDF

open-labeled, randomized trial compared PD with CVVHDF

Urea and creatinine clearance was higher with CVVHDF than PD.

PD showed better control of acid-base

Fluid correction was faster with CVVHDF.

Similar result for hyperkalemia and hemodynamic instability.

PD was cost-effective as compared with CVVHDF

Mortality 84% in CVVHDF versus 72% in PD ($P = 0.49$).

George J, Varma S, Kumar S et al. Comparing CVVHDF and PD in Critically ill patients with acute kidney injury: a pilot study.

Perit Dial Int 2011; 31: 422–429

# Comparing PD with CRRT

- RCT comparing two therapies in the ICU setting
- 50 patients randomised, 1:1, mean age 45
- Equally efficient in achieving metabolic and acid-base control
- Similar outcomes (high mortality);
  CRRT 80%, PD 70%)
- Cost of disposable: CRRT: INR 7184 ±1436 vs. PD INR 3009 ± 1643, $p < 0.001$ (US$1=INR 47)

*George V. et al. Perit Dial Int. 2011 Jul-Aug;31(4):422-9*

# A randomized clinical trial of high volume peritoneal dialysis versus extended daily hemodialysis for acute kidney injury patients

- 2 centres, RCT, 407 patients, 143 analysed
- Primary endpoint: in hospital mortality
- Secondary endpoints: recovery RRF, efficacy
- Difficulties with randomisation (unbalanced)
- Many exclusions – so generalisability not clear
- Metabolic control quicker with edHD
- RR of death using PD was 1.4 (CI 0.7-2.4, p = 0.19)

*Ponce D, Int Urol Nephrol. 2012*

# High-volume peritoneal dialysis in acute kidney injury: indications and limitations

- Prospective analysis of 204 treated patients (analysis in 150)
- 63.8±15.8 years, 70% ICU setting
- Sepsis main cause
- 57.3% dies, 20% recovered RRF
- Age, sepsis predicted death

## Summary

**Background and objectives** Peritoneal dialysis is still used for AKI in developing countries despite concerns about its limitations. The objective of this study was to explore the role of high-volume peritoneal dialysis in AKI patients in relation to metabolic and fluid control, outcome, and risk factors associated with death.

**Design, setting, participants, & measurements** A prospective study was performed on 204 AKI patients who were assigned to high-volume peritoneal dialysis (prescribed Kt/V=0.60/session) by flexible catheter and cycler; 150 patients (80.2%) were included in the final analysis.

**Results** Mean age was 63.8±15.8 years, 70% of patients were in the intensive care unit, and sepsis was the main etiology of AKI (54.7%). BUN and creatinine levels stabilized after four sessions at around 50 and 4 mg/dl, respectively. Fluid removal and nitrogen balance increased progressively and stabilized around 1200 ml and −1 g/d after four sessions, respectively. Weekly delivered Kt/V was 3.5±0.68. Regarding AKI outcome, 23% of patients presented renal function recovery, 6.6% of patients remained on dialysis after 30 days, and 57.3% of patients died. Age and sepsis were identified as risk factors for death. In urine output, increase of 1 g in nitrogen balance and increase of 500 ml in ultrafiltration after three sessions were identified as protective factors.

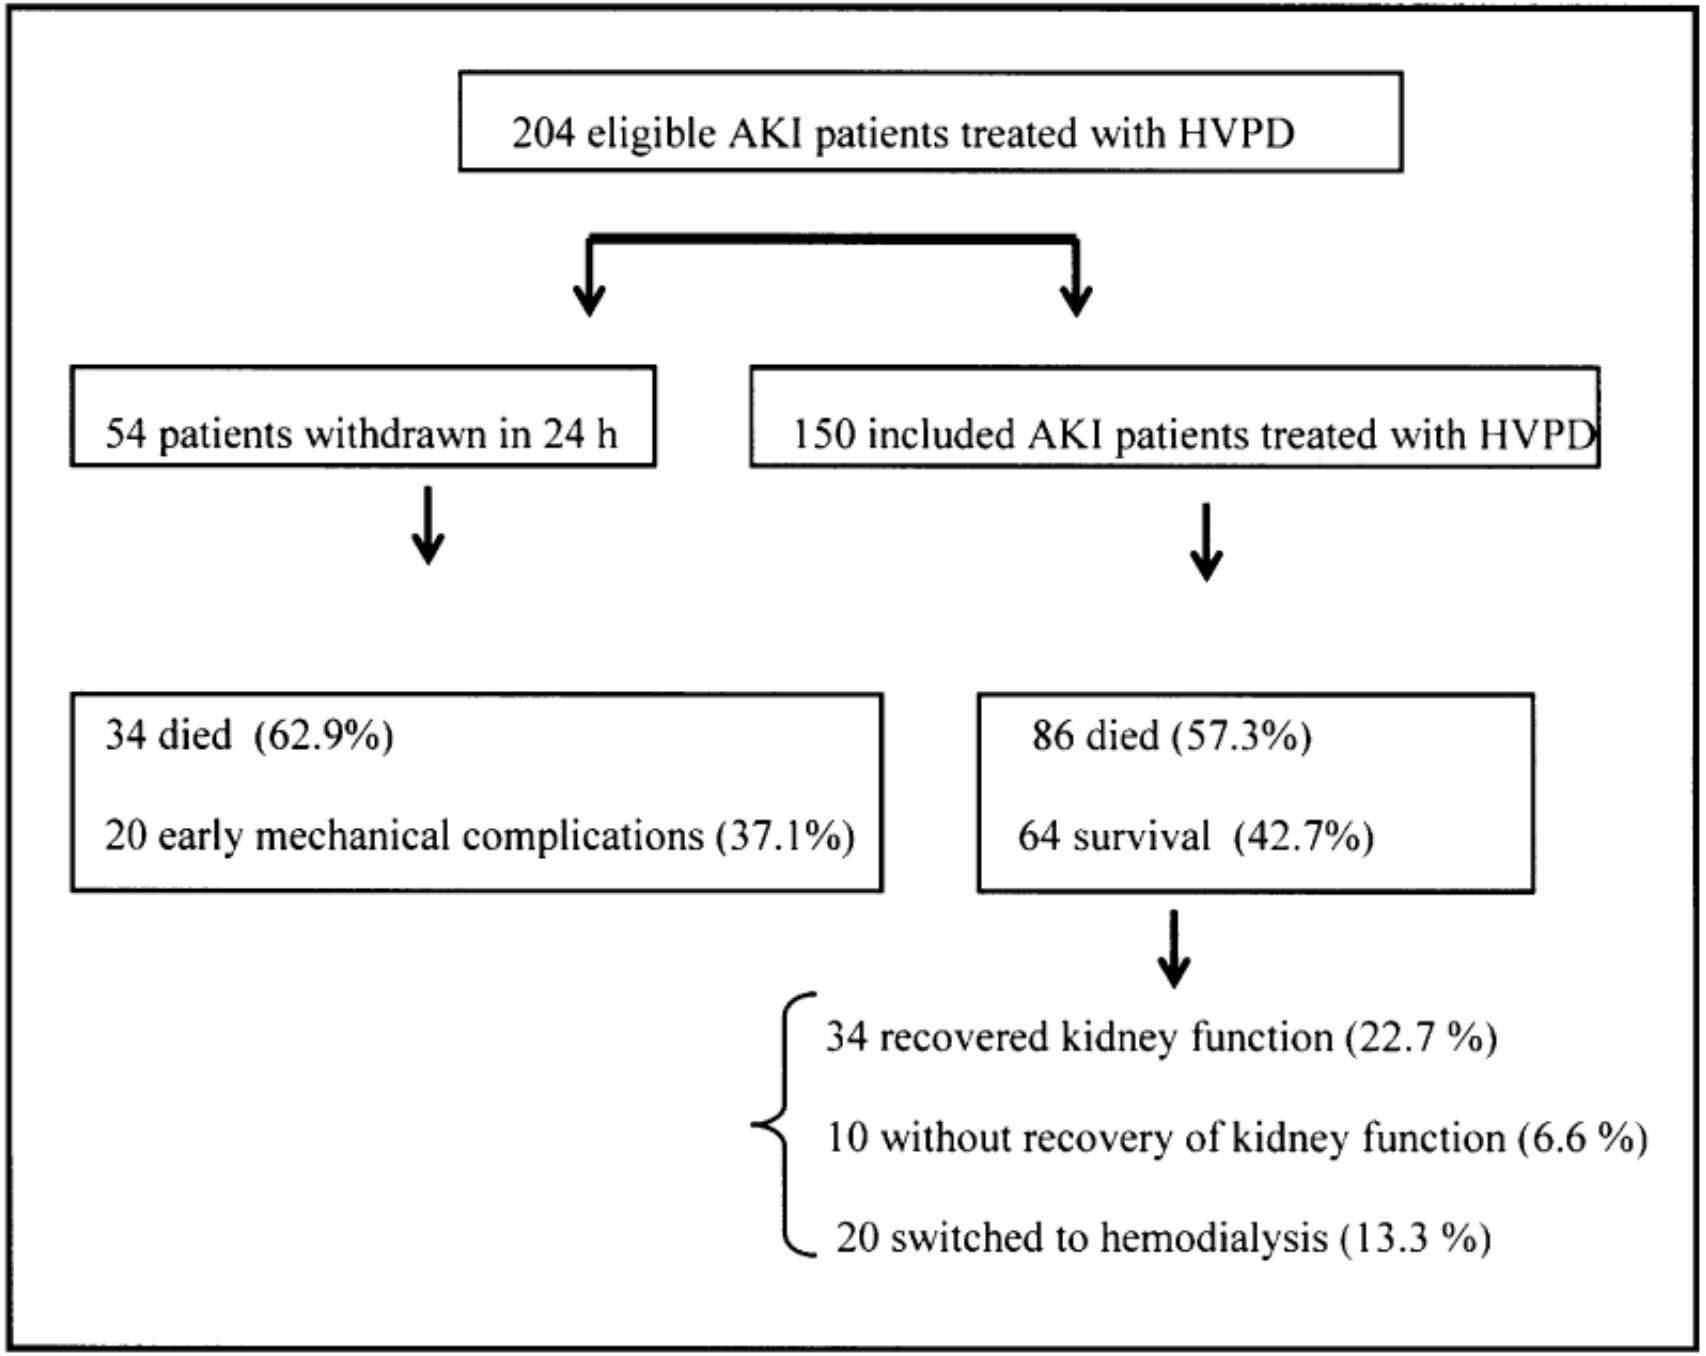
BUN and creatinine levels stabilized after four sessions at around 50 and 4 mg/dl, respectively. Fluid removal and nitrogen balance increased progressively and stabilized around 1200 ml and −1 g/d after four sessions, respectively. Weekly delivered Kt/V was 3.5±0.68. Regarding AKI outcome, 23% of patients presented renal function recovery, 6.6% of patients remained on dialysis after 30 days, and 57.3% of patients died. Age and sepsis were identified as risk factors for death. In urine output, increase of 1 g in nitrogen balance and increase of 500 ml in ultrafiltration after three sessions were identified as protective factors.



204 eligible AKI patients treated with HVPD
54 patients withdrawn in 24 h
150 included AKI patients treated with HVPD
34 died (62.9%)
20 early mechanical complications (37.1%)
86 died (57.3%)
64 survival (42.7%)
34 recovered kidney function (22.7 %)
10 without recovery of kidney function (6.6 %)
20 switched to hemodialysis (13.3 %)

# Limitations

- The limitation of this study was that the results were not presented according to **intention to treat**.

- Patients who changed the dialysis method (from HVPD to HD) were **excluded** to survival analysis.

# Conclusions

- High-volume peritoneal dialysis is effective for a selected AKI patient group, allowing adequate metabolic and fluid control.

- **Age, sepsis, and urine output** as well as **nitrogen balance and ultrafiltration** were associated significantly with death.

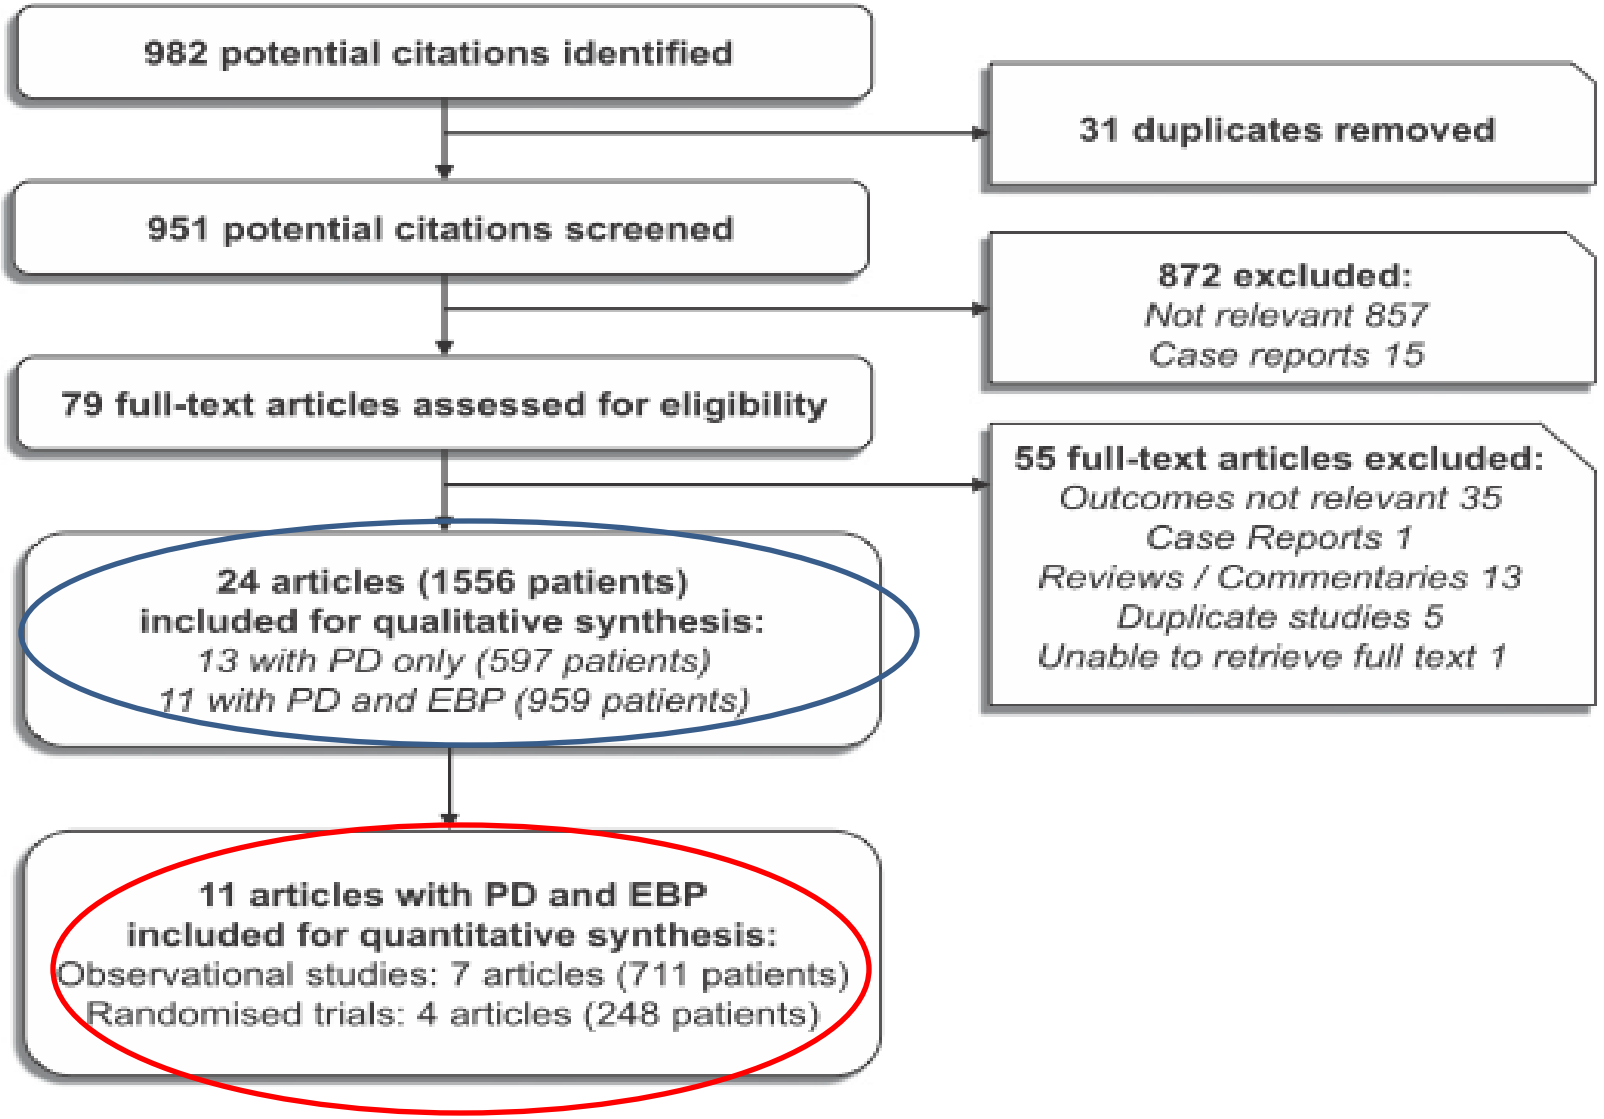
## Use of Peritoneal Dialysis in AKI: A Systematic Review

- Chang Yin Chionh,*† Sachin S. Soni,*‡ Fredric O. Finkelstein,§ Claudio Ronco,*| and Dinna N. Cruz|

# Study Selection



# Distribution of studies included for review

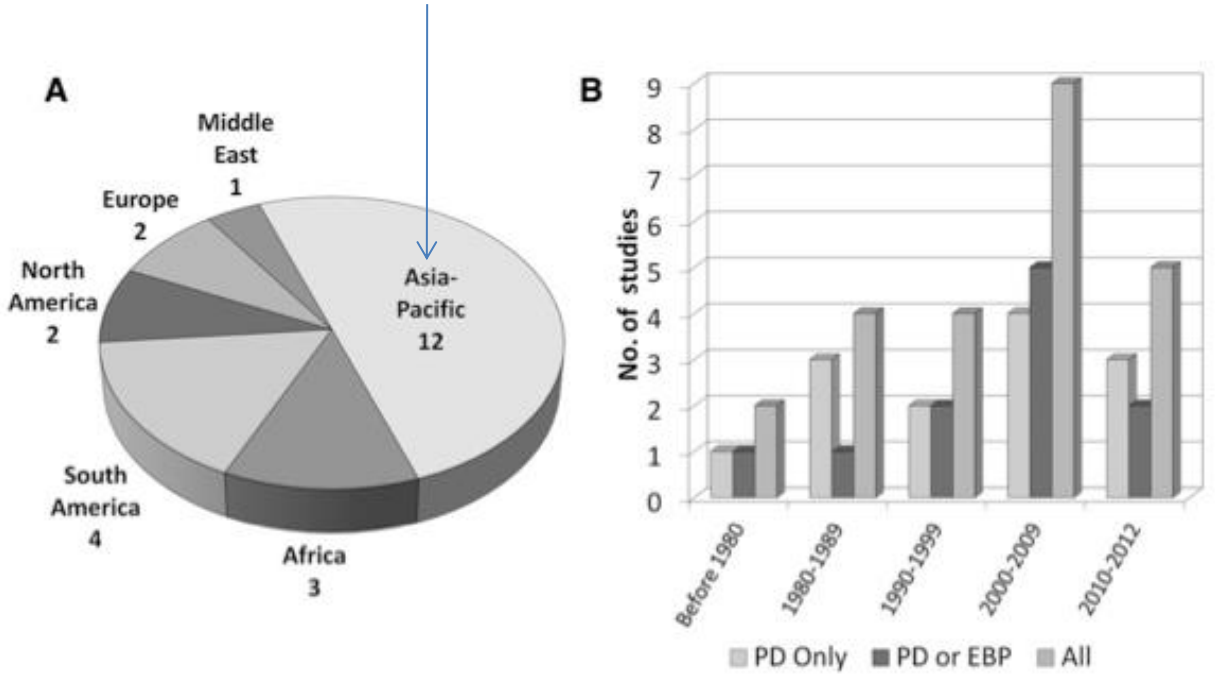


**Figure 2.** | Distribution of studies included for review. The number of studies is illustrated according to (A) geographical region of origin and (B) year of study publication. Australia is included under Asia–Pacific. EBP, extracorporeal blood purification; PD, peritoneal dialysis.

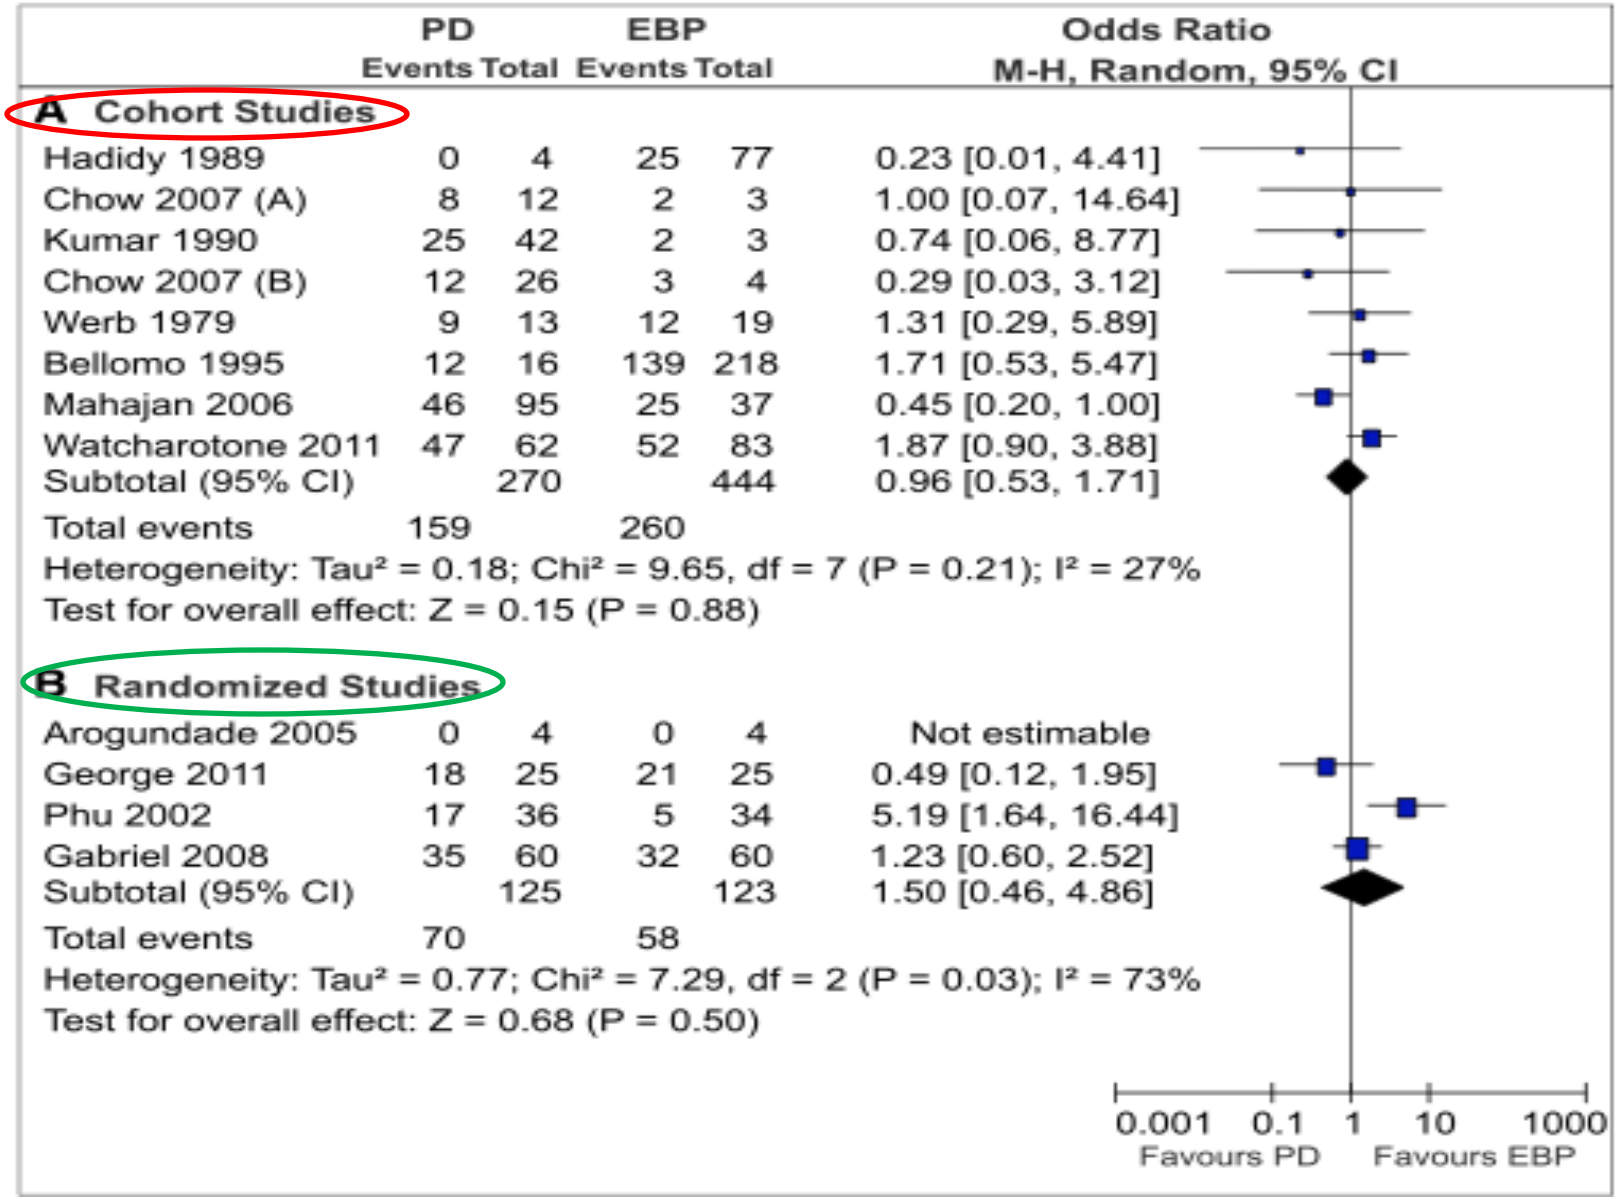
# Effect of renal replacement therapy modality on mortality in patients with AKI grouped by study design



# Conclusion & Discussion

❖**We had three main findings**.

- **First**, there is a paucity of good-quality data, with only four relatively small RCTs.
- **Second**, pooled analysis of 11 studies showed no difference in mortality between PD and EBP.
- **Third**, reporting was poor regarding PD dose and other important outcomes, such as renal recovery and PD-related complications.

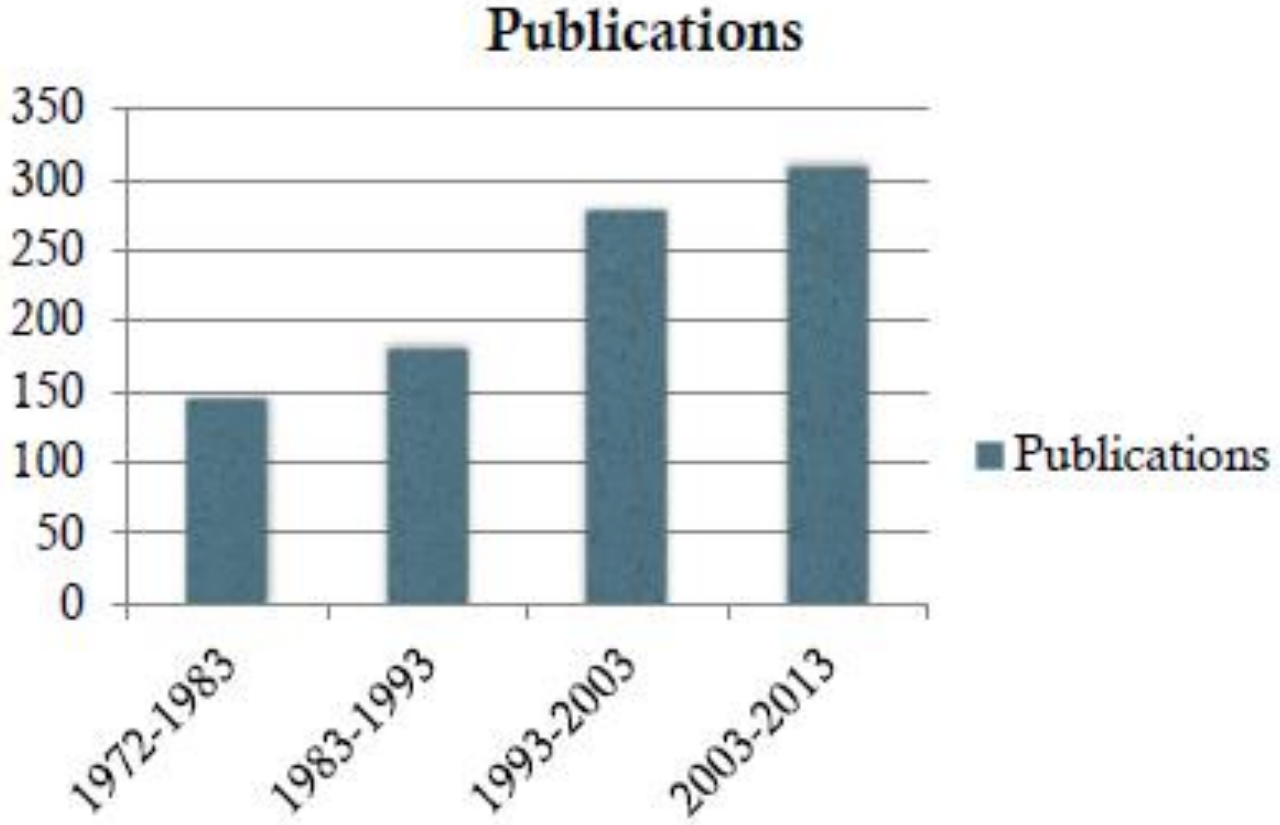
# Questions

- Is PD a suitable modality for treating AKI
- What is optimal access and fluid delivery for PD in AKI
- Which fluids should be used and what to do when not available
- How to dose PD for AKI
- Continuous flow PD

# Why do we need guidelines?



## ADULT GUIDELINES

### GUIDELINE A1: Suitability of peritoneal dialysis for AKI in adults

A1.1 Peritoneal dialysis should be considered as a suitable method of continuous renal replacement therapy in patients with acute kidney injury (1B).

### GUIDELINE P1: Suitability of PD for AKI in children

P1.1 Peritoneal dialysis is a suitable modality for RRT in AKI in children (1C).

# PD cost in Iran

- Until recently, the **cost of healthcare in the Iran** consumed almost 6.4% of the GDP

- The cost of PD comparing HD now in Iran is **20% more expensive**.

- 430,000,000 as compared with 350,000,000 Rials **US$ 12,500 vs 10,150 for HD**

- **12 years ago it was reversed**

# Economy of RRT Modalities in Iran
## *(Hemodialysis vs. Peritoneal Dialysis)*

Authors: Farhang ZangnehH., Manbachi M., Najafi I., Mehran Nikoo H., Keyvani M.

## INTRODUCTION

Health care expenditure in European countries varies between 11% of Gross Domestic Product (GDP) (Germany) and 6% of GDP (Luxemburg) whereas in Iran, this figure sums up to about 4% of the GDP. On the other hand, dialysis costs (in comparison to the total health budget) vary between 36% in France and 19% in Germany, while not more than 0.04% of the general population (on the average) is under dialysis. In previous studies performed by the MOH in Iran, CAPD (with an annual cost of around 70 million Rials) was introduced more expensive than hemodialysis (with an annual cost of around 48 million Rials) in the governmental sector. As this report contradicts completely with the information from other regions of the world, where CAPD is at least 30% less expensive than hemodialysis, we decided to have a second thought on this issue in Iran.

## MATERIAL AND METHODS

According to the international guidelines, we have classified all the related expenses into six general categories, summarized as below:

7th EuroPD meeting; Prague, Oct 2005 poster presentation

# Economy of RRT Modalities in Iran

(Hemodialysis vs. Peritoneal Dialysis)

Authors: Farhang ZangnehH., Manbachi M., Najafi I., Mehran Nikoo H., Keyvani M.

| Annual Costs Per Patient (in Rials and US Dollar) | Hemodialysis | CAPD |
|---|---|---|
| Hardware & Services | 11,927,644 | 891,694 |
| Physicians & Nurses | 11,576,500 | 4,052,137 |

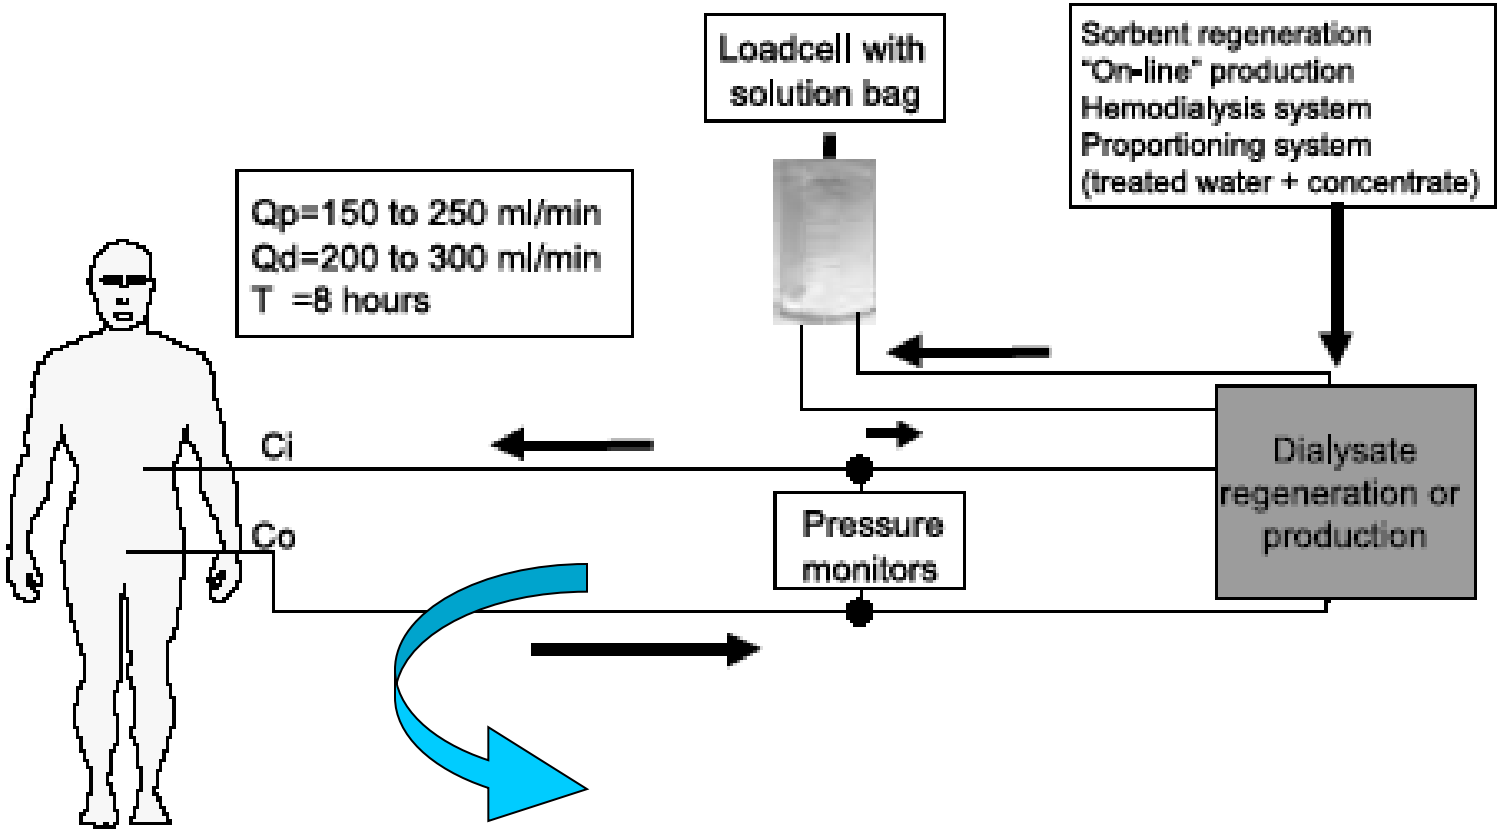
# Weekly Price of PD in ICU IRAN

- 300 ml/min * 60 min = 18000 ml = 9 * 2L Bag
- 9 * 2L Bag/1h * 30000 Tuman = 270,000 / 1h
- 270,000 * 10h = 2,700,000 Tuman/ session
- 2,700,000 * 7 days = 18,900,000 Tuman/week

# Schematic representation of the CFPD system



# PD in ICU

Iraj Najafi MD.

Fouman

11.2.1397

# Limitation of acute PD to specific indications

"Uncomplicated" or medical causes of ARF

- Glomerular diseases
- Drug-induced acute tubular necrosis
- Ischemic acute tubular necrosis if hemodynamically stable
- Hemolytic-uremic syndrome
- Infections such as leptospirosis
- Snake bites

Toxins

- Limited used in those drugs with low MW, small Vd, minimal protein binding, water soluble
  - Alcohols
  - NaCl intoxication
  - salicylates

40-60Kg – 2 litre 3 hourly cycles
>60kg – 2 litre 2 hourly cycles
Change to 4 hourly cycles once acidosis, pulmonary oedema and hyperkalaemia resolved
Add Heparin 500u /litre dialysate

Fluid overload with pulmonary oedema or severe hypertension – 4.25% dextrose

Mild fluid overload – alternate 1.5%/4.25% or use 2.5%

Euvolaemic or hypovolaemic – 1.5% dextrose

Measure potassium at least daily

If <4 mmol/l add 4 mmol/l to dialysate

Optimum care

Minimum standard

# CONCLUSION

- PD to treat patients with AKI provides an acceptable form of treatment. While PD is not used commonly in the developed world to treat patients with AKI, recent studies have suggested that outcomes with PD are as good as with extracorporeal RRTs. Certainly, in the developing world, there are major advantages for PD to manage patients with AKI. While the guidelines presented above focus on optimal treatment algorithms, it is important to keep in mind that treatment patterns need to be developed in accordance with individual patient needs taking into account the available resources and hospital environment. In low-resource settings, flexibility and appropriate adjustments in treatment patterns may need to be made.

# conclusion

- In conclusion, while waiting for better, multicenter comparative studies, there are many patients with acute kidney injury that may benefit from continuous, gentle affordable and efficient peritoneal dialysis.

# Conclusions

- There is currently no evidence to suggest significant differences in mortality between peritoneal dialysis and extracorporeal blood purification in AKI.

- There is a need for good-quality evidence in this important area.

# Lessons from PD/AKI Data

- PD is as effective as HD or CVVH to treat critically ill AKI patients
- Nephrologists can place catheters in these patients at bedside successfully
- Catheters work well if used right after placement – even with large volume PD cycling

# Problems of PD in the critically ill infant

- Respiratory distress
  - Splinting of diaphragm
  - Poor ultrafiltration with fluid overload
- Poor ultrafiltration
  - Decreased gut perfusion
  - Loss of osmotic gradient (sepsis)
