

# Smoking and kidney

Dr Anvar Mohammadi  
Nephrologist MUKS 1401

## SMOKING

- Reduces blood flow to the kidneys
- Thickens and hardens kidneys' renal arteries
- Brings in toxic chemicals
- Accelerates loss of kidney function

## DAMAGES YOUR KIDNEYS

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

The **prevalence** of cigarette smoking in 2015 was **16.7%** among adult males and **13.6%** among adult females . Prevalence was highest among adults aged **25–44 years** (14.8%) and lowest among persons aged  $\geq 65$  years

everyday **3800** youth under the age of 18 start smoking . Most adult smokers, **88%**, smoked their first cigarette before the age of 18

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

Cigarettes are designed to allow deep inhalation of smoke into the lungs, delivering high levels of nicotine to the brain within 10–20 s of inhalation

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

**Electronic cigarettes,** on the other hand, are rapidly increasing in use: approximately **28%** of high school students and 11% of middle school students are current electronic cigarette users.

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

(WHO) reports that among adults over 15 years, the global rate of smoking declined from 23.5% in 2007 to 20.7 in 2015, reflecting a 2.8% smoking rate reduction

the number of **people** smoking worldwide has remained at **1.1 billion** from 2007 to 2015 because of population growth

نفرتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

## نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

Smoking tobacco increases the risks for a wide range of chronic conditions, including cancer, cardiovascular diseases (coronary heart disease, stroke, and heart failure), respiratory diseases, and chronic kidney disease (CKD).

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

Population-based studies have identified cigarette smoking as an **independent risk factor** for various manifestations of CKD, including **proteinuria**, elevated serum creatinine levels, decreased **eGFR**, and development of ESKD or death associated with **CKD**

**Nicotine** acts as a ganglionic nicotinic **cholinergic agonist** in the autonomic ganglia, brain, spinal cord, neuromuscular junctions and adrenal medulla . Nicotine has **dose-dependent** pharmacological effects and has both **stimulant** and **depressant** action

The **effects of nicotine** on the central nervous system (CNS) and its peripheral stimulating effects are mediated through the release of several **neurotransmitters**, including acetylcholine, beta-endorphin, dopamine, norepinephrine, serotonin, and adrenocorticotrophic hormone (ACTH)

Notable **stimulant** effects of nicotine stimulant activities include peripheral vasoconstriction, elevated blood pressure, tachycardia, increased cardiac output, and enhanced mental alertness and cognitive function

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

**Depressant** effects of nicotine include muscle relaxation and anxiety reduction

Nicotine is well distributed with a volume of distribution of about 2.6 L/kg . It undergoes primarily **hepatic (80–90%) metabolism**—with the remainder of the metabolism taking place in the lungs and kidney—to inactive metabolite: cotinine. Nicotine has a **half-life of 1–4 h** and about 2–35% is excreted unchanged in the urine

# Cancer

Smoking is currently the largest preventable cause of cancer-related deaths, accounting for approximately 30% of cancer related deaths

A causal relationship has been established between cigarette (tobacco) smoking and lung cancer, the leading cause of cancer-related deaths in the U.S. There is also a causal relationship between cigarette smoking and cancers of the head, neck, liver, bladder, cervix, esophagus, colon, and rectum

# Cardiovascular Diseases

Major **mechanisms** underlying smoking-induced cardiovascular disease include endothelial dysfunction, prothrombotic effects, inflammation, altered lipid metabolism, increased demand for myocardial oxygen and blood, decreased supply of myocardial blood and oxygen, and insulin resistance

## Respiratory Diseases

smoking is the primary cause of **COPD** in the U.S

may exacerbate **asthma** in adults.

increases the risk of developing **tuberculosis** and dying from tuberculosis

# Additional Effects

impairs immune function, resulting in an increased risk of pulmonary infections and rheumatoid arthritis

increasing the risk of peptic ulcer disease.

smokers with diabetes have a higher risk of developing complications, including nephropathy, blindness, peripheral neuropathy, and amputations

Cigarette smoke damages a wide range of immunological functions, including **innate and adaptive** immune responses

Emerging literature demonstrates that **inflammasome** constitutes an essential component in innate immune response.

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

smoking plays an important role in promoting worsening of proteinuria and progression of diabetic nephropathy, particularly in type I diabetes (T1DM)

effects of **NIC** on glomerular renal disease are at least in part mediated by **direct injurious effects** of NIC on glomerular podocytes, including increased generation of reactive oxygen species (**ROS**), apoptosis, and reduced synaptopodin (**SYNPO**), a major molecule involved in the stabilization of the glomerular basement membrane.

**NIC** Potentiates oxLDL-Induced **Podocyte**  
**Apoptosis** Through a **CD36**-Dependent  
Mechanism

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

**NIC** upregulates the expression of CD36 in human THP1-differentiated macrophages

CD36 is involved in the regulation of lipid metabolism associated with oxLDL in podocytes and that NIC **enhances CD36-mediated lipid accumulation in human podocytes** through upregulation of CD36.

the administration of **NIC** to wild-type mice had no significant effect on **fibronectin expression** but resulted in a significant **increase** in fibronectin in diabetic mice.

while foci of **cortical scarring** were observed in 50% of diabetic mice on tap water, 100% of diabetic mice on NIC had evidence of cortical scarring.

Smoking  
harms  
your  
kidneys!

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

## Potential Mechanisms of Smoking-Induced Renal Damage

Possible mechanisms whereby cigarette smoking may contribute to renal damage include sympathetic nervous system activation

glomerular capillary hypertension,

Endothelial cell injury, and direct tubulotoxicity.

***Smoking***

**Sympathoadrenal activation**

**Increase in circulating catecholamines**

**$\beta$ 1-adrenergic stimulation**

**Increase in renin production**

***Angiotensin II***

نفرتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

Most of the effects of tobacco exposure are **dose and time dependent** and could be ameliorated with smoking cessation.

**nicotine** has powerful mitogenic effects and induces **extracellular matrix production** in human **mesangial cells** via reactive oxygen species generation. These effects of nicotine may play a major role in the pathogenic **mechanisms** that mediate the deleterious effects of smoking in renal disease.

# CIGARETTE SMOKING AND BLOOD PRESSURE

## Acute effects

are related to **sympathetic** nervous system overactivity, which leads to an increase in blood pressure, heart rate, myocardial contractility, and myocardial oxygen consumption

The rise in blood pressure with each cigarette is **transient**, and this transient increase may be most prominent with the first cigarette of the day, even in those who smoke cigarettes habitually.

the average elevation in **systolic** pressure after the first cigarette of the day was approximately **20 mmHg**

Blood pressure began to fall **10 to 15 minutes** after smoking ceased, and no pressor effect was detected after **30 minutes**.

# Chronic effects of cigarette smoking

There are inconsistent data that cigarette smoking raises blood pressure chronically or increases the incidence of hypertension.

In many, but not all studies, individuals who smoke cigarettes habitually had **lower blood pressure** than nonsmokers

This finding might be related to the following:

- Those who smoke cigarettes generally have **a lower body weight** compared with those who do not smoke

**Cotinine**, the major metabolite of nicotine, has a **vasodilator** effect that might also contribute to lower blood pressure in those who smoke

However, cigarette smoking increases the risk of masked hypertension

Cigarette smoking increases arterial stiffness, which may persist for a decade after smoking cessation

Cigarette smoking increases the risk of renovascular hypertension

Several studies documented that smoking is an independent **predictor of (micro)albuminuria** in otherwise healthy hypertensive subjects. The prevalence of microalbuminuria is almost **double** in smoking than nonsmoking lean patients with primary hypertension (**12**).

A recent study ([15](#)) found that patient hypertension and left ventricular hypertrophy smoking >20 cigarettes/d had a 1.6-fold higher prevalence of **microalbuminuria** and a 3.7-fold higher prevalence of **macroalbuminuria** than never-smokers

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

Cigarette smoking is associated with **severe hypertensive retinopathy** (often called "malignant hypertension") ; whether or not this relation is the result of renovascular hypertension is unknown.

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

Although smoking may **not increase the risk of new-onset hypertension**, it markedly increases the risk of atherosclerotic cardiovascular events and end-stage kidney disease in patients with hypertension

The mechanism underlying the adverse effect on kidney function is unclear but may be related to smoking-induced, transient **increases** in systemic blood **pressure** that are then transmitted to the **glomerulus**, resulting in glomerular hypertension

**e-cigarettes** are associated with a mild, short-term increase in **diastolic pressure** and a mild, short-term increase or no effect on systolic blood pressure

In a retrospective, case-control study of 89 cigarette smokers with hypertension, switching from combustible tobacco cigarettes to e-cigarettes was associated with a reduction in systolic and diastolic blood pressure at 12 months (-10 mmHg and -6 mmHg, respectively)

# HOOKAH (WATER PIPE) SMOKING AND BLOOD PRESSURE

indirect and direct evidence suggest that hookah smoking has blood pressure and other cardiovascular effects **similar** to cigarette smoking.

hookah smoking for 15 to 30 minutes acutely increased systolic pressure (by 3 to 16 mmHg) and diastolic pressure (by 2 to 14 mmHg)

# Adverse Renal Effects of Smoking in Patients with Renal Disease

## Diabetic Nephropathy

The first reports that documented an increased renal risk in smokers were retrospective studies in patients with type 1 diabetes. In 1978, Christiansen ([18](#)) provided evidence that smokers have a **higher risk** to develop diabetic nephropathy than nonsmokers.

Diabetic nephropathy was present in 13% of patients who smoked <10 cigarettes/d but in >25% in patients who smoked 30 cigarettes/d. Subsequently, numerous studies confirmed the increased renal risk in smokers with type 1 and type 2 diabetes mellitus

The available literature documents that smoking (1) increases the risk to develop microalbuminuria (14,20-30), (2) accelerates the rate of progression from microalbuminuria to manifest proteinuria (31-36), and (3) accelerates progression of renal failure (32,37-40).

Chase *et al.* ([20](#)) reported that in a group of 359 young subjects with type 1 diabetes the prevalence of borderline ( $>7.6 \mu\text{g}/\text{min}$ ) and frankly elevated ( $>30 \mu\text{g}/\text{min}$ ) urinary albumin excretion rate was **2.8-fold** higher in smokers than nonsmokers.

the impact of smoking on the rate of progression is similar in type 2 diabetes. The rate of decline in GFR is approximately 55% higher in smokers compared with nonsmokers.

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

Hypertension, hyperglycemia, dyslipidemia, and cigarette smoking (CS) are major risk factors that contribute to the progression of diabetic nephropathy (DN).

stable **reactive aldehydes** in CS induce endothelial injury via mechanisms that involve activation of NADPH oxidase and increased oxidative stress

# *Nondiabetic Renal Disease*

## PRIMARY RENAL DISEASE

at entry was related to the decline in GFR after 3.2 yr of follow-up: in patients with chronic glomerulonephritis, the loss of GFR was **5.3** ml/min per yr in heavy smokers but only 2.5 ml/min per yr in nonsmokers. Thus, smoking appears to **double** the rate of **progression** in patients with chronic glomerulonephritis

## SYSTEMIC DISEASES INVOLVING THE KIDNEY

A retrospective cohort study on 160 patients with a median follow-up of 6.4 yr documented [redacted] at the time of onset of lupus nephritis was an independent risk factor for **more rapid progression** to ESRD ([55](#)).

The hypothesis that the presence of ANCA-positive crescentic glomerulonephritis has been forwarded (57) but without supporting data.

smoking-induced endothelial cell damage may predispose to the formation of antibodies against nuclear cell antigens extruded from endothelial cells or endothelial cell adherent polynuclear cells.

in passing that in patients with anti-glomerular basement membrane glomerulonephritis smoking strikingly **increases the risk of pulmonary hemorrhage** (Goodpasture syndrome) ([1](#))

a combination of **arteriolar and atheroembolic damage** (i.e., cholesterol microembolism) is thought to contribute to progressive **loss of renal function**. Smoking is a known **risk factor** for cholesterol microembolism ([64](#))

## Smoking and Atherosclerotic Renal Artery Stenosis/Ischemic Nephropathy

The prevalence of renal vascular stenosis is **higher** in patients with peripheral vascular disease ([59](#)). The latter is common in smokers; it is not therefore surprising that smokers have a higher risk of critical atherosclerotic renal artery stenosis ([60,61](#)).

a high proportion of patients with unilateral ([62](#)) or bilateral ([63](#)) atherosclerotic renal artery stenosis are smokers

## Pathohistologic Features of Smoking-Induced Renal Damage

In a renal biopsy study, the histologic findings of 107 patients with chronic renal failure were assessed to investigate the effect of smoking on glomerulosclerosis and vascular damage (72)

Smoking was **not** associated with **the severity of glomerulosclerosis**.

Compared with nonsmokers, ever-smokers exhibited **more severe myointimal hyperplasia**. This finding was particularly evident in patients >50 yr of age.

our group found more severe **glomerulosclerosis** and **tubulointerstitial fibrosis** in the subtotally nephrectomized rat treated with a cigarette smoke extract dissolved in acetone ([74](#))

glomerular  
basement width in patients with  
type 2 diabetes who smoke has been  
reported in a preliminary biopsy  
study ([75](#)).

## Excess risk of renal allograft loss associated with cigarette smoking

Pretransplant smoking was significantly associated with **reduced** overall graft and death-censored **graft survival**.

Patients who were smokers at the time of pretransplant evaluation had kidney graft survival of 84%, 65%, and 48% at 1, 5, and 10 years, respectively, compared with graft survival in nonsmokers of 88%, 78%, and 62% ( $P=0.007$ ).

In a multivariate analysis, pretransplant smoking was associated with a relative risk of **2.3** for graft loss

Among patients with a smoking history before transplantation, death-censored graft **survival** was significantly **higher** for those who **quit** smoking before transplant evaluation.

Cigarette smoking is associated with **higher eGFR** compared to non-smoking. This difference was more pronounced in males than females

The higher prevalence of **proteinuria** in smokers suggests a mechanism of **hyperfiltration**, which might result in **future progressive renal damage**

## Cigarette smoking in living kidney donors: donor and recipient outcomes

Donor smoking at time of evaluation did not significantly decrease allograft survival (HR = 1.19,  $p = 0.52$ ), but **recipient smoking** at evaluation did **reduce** allograft **survival** (HR = 1.74,  $p = 0.05$ ).

**Both** donor and recipient smoking **decreased** recipient survival (HR = 1.93,  $p < 0.01$  vs HR = 1.74,  $p = 0.048$ ).

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

## Cigarette Smoking and Its Hazards in Kidney Transplantation

Kidney **donors** with history of cigarette smoking are prone to develop **perioperative complications**, pneumonia, and wound infection.

نفراتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

## Smoking and its effects in kidney transplantation

### Donor

- (i) More perioperative complications
- (ii) More postoperative wound infection
- (iii) Less likely to provide follow-up informations
- (iv) High creatinine at the end of 1 year
- (v) Higher death rate in donor with history of smoking

### Recipient

- (i) High risk of cardiovascular disease
- (ii) Reduced graft survival
- (iii) Reduced kidney transplant recipient survival
- (iv) ? more rejection
- (v) More chances of Legionnaires, disease, influenza, varicella pneumonitis, BK virus, and tuberculosis
- (vi) High risk of invasive cancer including lung, skin, and bladder cancer

## Cigarette smoking may accelerate the progression of IgA nephropathy

cigarette smoking (hazard ratio (HR) = 1.58;  $p = 0.043$ ) was an independent risk factor predicting poor renal progression in IgAN, and that IgAN patients with chronic kidney disease (CKD) **stage 3-4** were more susceptible to cigarette smoking ( $p < 0.001$ )

A case–control study revealed that smoking contributed to the **progression to chronic renal failure**, especially regarding nephrosclerosis and glomerulonephritis

We divided the patients into non-smoker and smoker (current or former) groups. Smoker was defined as having actively smoked > 400 cigarettes in a patient's lifetime

The correlation analyses indicated that smoking was correlated **with tubular atrophy/interstitial fibrosis** lesions (odds ratio (OR) = 1.826; 95% CI: 1.296–2.573;  $p = 0.001$ ) but not with other pathological lesions.

smoking dose was negatively correlated with **eGFR** ( $r = 0.141$ ;  $p < 0.001$ ) and positively correlated with **proteinuria** ( $r = 0.096$ ;  $p = 0.001$ ).

analysis showed that cigarette smoking remained an independent **risk factor for IgAN progression**

Smokers with  $> 20$  pack-years tended to have higher proportions of tubular atrophy/interstitial fibrosis.

Further analysis showed that patients with more severe **renal dysfunction** were more susceptible to the effects of cigarette smoking

Further analysis indicated that smokers with **hypertension** and **renal vasculopathy** had the worst renal outcomes (before or after PSM), indicating that cigarette smoking, hypertension, and renal vasculopathy could **accelerate** IgAN **progression**

Smoking could induce oxidative stress and increase the stiffness of central vessels, causing tubular damage and increasing the risk of tubular atrophy and fibrosis

IgAN patients with stage 3 or 4 CKD should undergo smoking cessation therapy to slow deterioration of the renal disease.

smoking

**cessation** was associated with less progression to macroalbuminuria and a slower rate of GFR decline than continued smoking in patients with diabetes

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

smoking was associated with increased all-cause mortality as well as the combined endpoint of all-cause mortality and CKD progression, though CKD progression alone

نفروتوکسین‌ها و کلیه

Kidney and Nephrotoxins

۱۳-۱۵ مهر ۱۴۰۱-تهران

## Prevalence of Cigarette Smoking among Patients with Different Histologic Types of Kidney Cancer

Cigarette smoking is causally linked to renal cell carcinoma (RCC).

By histology, proportions of current or formers smokers ranged from 38% in patients with chromophobe carcinoma to 61.9% in those with collecting duct/medullary carcinoma.

Compared with other RCC histologic types, chromophobe RCC has a weaker (if any) association with smoking.

it is rational to conclude that **hemodialysis** is one of the **single most effective** measures to retard progression of renal failure—quite apart from its undoubtedly beneficial effect on cardiovascular risk ([67,85](#)).
